

# The **xint** bundle

JEAN-FRAN OIS BURNOL

jfbu (at) free (dot) fr

Package version: 1.09i (2013/12/18)

**xinttools** is loaded by **xint** (hence by all other packages of the bundle, too): it provides utilities of independent interest such as expandable and non-expandable loops.

**xint** implements with expandable  $\text{\TeX}$  macros additions, subtractions, multiplications, divisions and powers with arbitrarily long numbers.

**xintfrac** extends the scope of **xint** to decimal numbers, to numbers in scientific notation and also to fractions with arbitrarily long such numerators and denominators separated by a forward slash.

**xintexpr** extends **xintfrac** with an expandable parser  $\text{\xintexpr} \dots \text{\relax}$  of expressions involving arithmetic operations in infix notation on decimal numbers, fractions, numbers in scientific notation, with parentheses, factorial symbol, function names, comparison operators, logic operators, twofold and threefold way conditionals, sub-expressions, macros expanding to the previous items.

Further modules:

**xintbinhex** is for conversions to and from binary and hexadecimal bases.

**xintseries** provides some basic functionality for computing in an expandable manner partial sums of series and power series with fractional coefficients.

**xintgcd** implements the Euclidean algorithm and its typesetting.

**xintcfrac** deals with the computation of continued fractions.

Most macros, and all of those doing computations, work purely by expansion without assignments, and may thus be used almost everywhere in  $\text{\TeX}$ .

The packages may be used with any flavor of  $\text{\TeX}$  supporting the  $\varepsilon$ - $\text{\TeX}$  extensions.  $\text{L}\text{\TeX}$  users will use  $\text{\usepackage}$  and others  $\text{\input}$  to load the package components.

## 1 Quick introduction

The `xint` bundle consists of the three principal components `xint`, `xintfrac` (which loads `xint`), and `xintexpr` (which loads `xintfrac`), and four additional modules. Release 1.09g has moved the macros of `xint` not dealing with the manipulation of big numbers to a separate package `xinttools` (which is automatically loaded by `xint`), of independent interest.

All components may be used as regular packages with L<sup>A</sup>T<sub>E</sub>X or loaded directly via \input (e.g. \input xint.sty\relax) in any other format based on T<sub>E</sub>X. Each of them automatically loads those not already loaded it depends on.

The  $\varepsilon$ -T<sub>E</sub>X extensions must be enabled; this is the case in modern distributions by default, except if you invoke T<sub>E</sub>X under the name `tex` in command line (`etex` should be used then, or `pdftex` in DVI output mode).

The goal is to compute *exactly*, purely by expansion, without count registers nor assignments nor definitions, with arbitrarily big numbers and fractions. The only non-algebraic operation which is currently implemented is the extraction of square roots.

The package macros expand their arguments<sup>1</sup>; as they are themselves completely expandable, this means that one may nest them arbitrarily deep to construct complicated (and still completely expandable) formulas. But one will presumably prefer to use the (expandable!) `\xintexpr ... \relax` parser as it allows infix notations, function names (corresponding to some of the package macros), comparison operators, boolean operators, 2way and 3way conditionals, unpacking of count and dimen registers or variables...

When producing very long numbers there is the question of printing them on the page, without going beyond the page limits. In this document, I have most of the time made use of these macros (not provided by the package):

```
\def\allowsplits #1%
{ \ifx #1\relax \else #1\hspace{0pt plus 1pt}\relax\expandafter\allowsplits\fi }%
\def\printnumber #1{ \expandafter\expandafter\expandafter\allowsplits #1\relax }%
% (all macros from the xint bundle expand in two steps to their final output).
```

An alternative (footnote 9) is to suitably configure the thousand separator with the `numprint` package (does not work in math mode; I also tried `sinput` but even in text mode could not get it to break numbers across lines). Recently I became aware of the `seqsplit` package<sup>2</sup> which can be used to achieve this splitting across lines, and does work in inline math mode.

The utilities provided by `xinttools` (section 26), some completely expandable, others not, are of independent interest. Their use is illustrated through various examples: among those, it is shown in subsection 26.27 how to implement in a completely expandable way the quick sort algorithm and also how to illustrate it graphically. Other examples include some dynamically constructed alignments with automatically computed prime number cells (subsection 26.11, subsection 26.21).

Some other computational examples are the computations of  $\pi$  and  $\log 2$  using `xint` and the computation of the convergents of  $e$  with the further help of the `xintcfrac` package.

## 2 Recent changes

Release 1.09i ([2013/12/18])

- `\xintiiexpr` is a variant of `\xintexpr` which is optimized to deal only with (long) integers, / does a euclidean quotient.
- `\xintnumexpr`, `\xintthenumexpr`, `\xintNewNumExpr` are renamed, respectively, `\xintexpr`, `\xinttheexpr`, `\xintNewIExpr`. The earlier denominations are kept but to be removed at some point.
- it is now possible within `\xintexpr... \relax` and its variants to use count, dimen, and skip registers or variables without explicit `\the\|number`: the parser inserts automatically `\number` and a tacit multiplication is implied when a register or variable immediately follows a number or fraction. Regarding dimensions and `\number`, see the further discussion in section 12.
- new conditional `\xintifOne`; `\xintifTrueFalse` renamed to `\xintifTrueAelseB`; new macros `\xintTFrac` ('fractional part', mapped to function `frac` in `\xintexpr`-essions), `\xintFloatE`.
- `\xintAssign` admits an optional argument to specify the expansion type to be used: [] (none), [o] (once), [oo] (twice), [f] (full), others, to define the macros (the default is [e] which means to use `\edef`).
- related to the previous item, `xinttools` defines (only if the names have not already been assigned) `\odef`, `\oodef`, `\fdef`. These tools are provided for the case one uses the package macros in a non-expandable context, particularly `\oodef` which expands twice the macro replacement text and is thus a faster alternative to `\edef` taking into account that the `xint` bundle macros expand already completely in only two steps. This can be significant when repeatedly making (re)-definitions expanding to hundreds of digits.

---

<sup>1</sup>see in section 7 the related explanations.

<sup>2</sup><http://ctan.org/pkg/seqsplit>

## 2 Recent changes

- some across the board slight efficiency improvement as a result of modifications of various types to “fork” macros and “branching conditionals” which are used internally.
- bug-fix: `\xintAND` and `\xintOR` inserted a space token in some cases and did not expand as promised in two steps (bug dating back to 1.09a I think; this bug was without consequences when using `&` and `|` in `\xintexpr`-essions, it affected only the macro form) :-((.
- bug-fix: `\xintFtoCCv` still ended fractions with the `[0]`'s which were supposed to have been removed since release 1.09b.

For a more detailed change history, see [section 25](#). Main recent additions:

Release 1.09h ([2013/11/28]):

- all macros of `xinttools` for which it makes sense are now declared `\long`.

Release 1.09g ([2013/11/22]):

- package `xinttools` is detached from `xint`, to make tools such as `\xintFor`, `\xintApplyUnbraced`, and `\xintiloop` available without the `xint` overhead.
- new expandable nestable loops `\xintloop` and `\xintiloop`.

Release 1.09f ([2013/11/04]):

- new `\xintZapFirstSpaces`, `\xintZapLastSpaces`, `\xintZapSpaces`, `\xintZapSpacesB`, for expandably stripping away leading and/or ending spaces.
- `\xintCSVtoList` by default uses `\xintZapSpacesB` to strip away spaces around commas (or at the start and end of the comma separated list).
- also the `\xintFor` loop will strip out all spaces around commas and at the start and the end of its list argument; and similarly for `\xintForpair`, `\xintForthree`, `\xintForfour`.
- `\xintFor et al.` accept all macro parameters from #1 to #9.

Release 1.09e ([2013/10/29]):

- new `\xintintegers`, `\xintdimensions`, `\xintrationals` for infinite `\xintFor` loops, interrupted with `\xintBreakFor` and `\xintBreakForAndDo`.
- new `\xintifForFirst`, `\xintifForLast` for the `\xintFor` and `\xintFor*` loops,
- the `\xintFor` and `\xintFor*` loops are now `\long`, the replacement text and the items may contain explicit `\par`'s.
- new conditionals `\xintifCmp`, `\xintifInt`, `\xintifOdd`.
- the documentation has been enriched with various additional examples, such as the [the quick sort algorithm illustrated](#) or the computation of prime numbers ([subsection 26.11](#), [subsection 26.14](#), [subsection 26.21](#)).

Release 1.09c ([2013/10/09]):

- added `bool` and `togl` to the `\xintexpr` syntax; also added `\xintboolexpr` and `\xintifboolexpr`.
- `\xintFor` is a new type of loop, whose replacement text inserts the comma separated values or list items via macro parameters, rather than encapsulated in macros; the loops are nestable up to four levels, and their replacement texts are allowed to close groups as happens with the tabulation in alignments,
- `\xintApplyInline` has been enhanced in order to be usable for generating rows (partially or completely) in an alignment,
- new command `\xintSeq` to generate (expandably) arithmetic sequences of (short) integers,

Release 1.09a ([2013/09/24]):

- `\xintexpr..\relax` and `\xintfloatexpr..\relax` admit functions in their syntax, with comma separated values as arguments, among them `reduce`, `sqr`, `sqrt`, `abs`, `sgn`, `floor`, `ceil`, `quo`, `rem`, `round`, `trunc`, `float`, `gcd`, `lcm`, `max`, `min`, `sum`, `prd`, `add`, `mul`, `not`, `all`, `any`, `xor`.
- comparison (`<`, `>`, `=`) and logical (`l`, `&`) operators.
- `\xintNewExpr` now works with the standard macro parameter character `#`.
- both regular `\xintexpr`-essions and commands defined by `\xintNewExpr` will work with comma separated lists of expressions,

### 3 Overview

- new commands `\xintFloor`, `\xintCeil`, `\xintMaxof`, `\xintMinof` (package `xintfrac`), `\xintGCDof`, `\xintLCM`, `\xintLCMof` (package `xintgcd`), `\xintifLt`, `\xintifGt`, `\xintifSgn`, `\xintANDof`, ...
- The arithmetic macros from package `xint` now filter their operands via `\xintNum` which means that they may use directly count registers and `\numexpr`-essions without having to prefix them by `\the`. This is thus similar to the situation holding previously but with `xintfrac` loaded.

See section 25 for more.

## 3 Overview

The main characteristics are:

1. exact algebra on arbitrarily big numbers, integers as well as fractions,
2. floating point variants with user-chosen precision,
3. implemented via macros compatible with expansion-only context.

‘Arbitrarily big’: this means with less than  $2^{31}-1=2147483647$  digits, as most of the macros will have to compute the length of the inputs and these lengths must be treatable as  $\text{\TeX}$  integers, which are at most 2147483647 in absolute value. This is a distant theoretical upper bound, the true limitation is from the *time* taken by the expansion-compatible algorithms, this will be commented upon soon.

As just recalled, ten-digits numbers starting with a 3 already exceed the  $\text{\TeX}$  bound on integers; and  $\text{\TeX}$  does not have a native processing of floating point numbers (multiplication by a decimal number of a dimension register is allowed — this is used for example by the `pgf` basic math engine.)

$\text{\TeX}$  elementary operations on numbers are done via the non-expandable *advance*, *multiply*, and *divide* assignments. This was changed with  $\varepsilon$ - $\text{\TeX}$ ’s `\numexpr` which does expandable computations using standard infix notations with  $\text{\TeX}$  integers. But  $\varepsilon$ - $\text{\TeX}$  did not modify the  $\text{\TeX}$  bound on acceptable integers, and did not add floating point support.

The `bigintcalc` package by HEIKO OBERDIEK provided expandable operations (using some of `\numexpr` possibilities, when available) on arbitrarily big integers, beyond the  $\text{\TeX}$  bound. The present package does this again, using more of `\numexpr` (`xint` requires the  $\varepsilon$ - $\text{\TeX}$  extensions) for higher speed, and also on fractions, not only integers. Arbitrary precision floating points operations are a derivative, and not the initial design goal.<sup>3,4</sup>

The L<sup>A</sup>T<sub>E</sub>X3 project has implemented expandably floating-point computations with 16 significant figures (`l3fp`), including special functions such as exp, log, sine and cosine.

The `xint` package can be used for 24, 40, etc... significant figures but one rather quickly (not much beyond 100 figures perhaps) hits against a ‘wall’ created by the constraint of expandability: currently, multiplying out two one-hundred digits numbers takes circa 80 or 90 times longer than for two ten-digits numbers, which is reasonable, but multiplying out two one-thousand digits numbers takes more than 500 times longer than for two one

<sup>3</sup>currently (v1.08), the only non-elementary operation implemented for floating point numbers is the square-root extraction; furthermore no NaN’s nor error traps has been implemented, only the notion of ‘scientific notation with a given number of significant figures’.

<sup>4</sup>multiplication of two floats with  $P=\text{\xinttheDigits}$  digits is first done exactly then rounded to  $P$  digits, rather than using a specially tailored multiplication for floating point numbers which would be more efficient (it is a waste to evaluate fully the multiplication result with  $2P$  or  $2P-1$  digits.)

## 4 Missing things

hundred-digits numbers. This shows that the algorithm is drifting from quadratic to cubic in that range. On my laptop multiplication of two 1000-digits numbers takes some seconds, so it can not be done routinely in a document.<sup>5</sup>

The conclusion perhaps could be that it is in the end lucky that the speed gains brought by **xint** for expandable operations on big numbers do open some non-empty range of applicability in terms of the number of kept digits for routine floating point operations.

The second conclusion, somewhat depressing after all the hard work, is that if one really wants to do computations with *hundreds* of digits, one should drop the expandability requirement. And indeed, as clearly demonstrated long ago by the [pi computing file](#) by D. ROEGEL one can program  $\text{\TeX}$  to compute with many digits at a much higher speed than what **xint** achieves: but, direct access to memory storage in one form or another seems a necessity for this kind of speed and one has to renounce at the complete expandability.<sup>6 7</sup>

## 4 Missing things

‘Arbitrary-precision’ floating-point operations are currently limited to the basic four operations, the power function with integer exponent, and the extraction of square-roots.

## 5 Some examples

The main initial goal is to allow computations with integers and fractions of arbitrary sizes.

Here are some examples. The first one uses only the base module **xint**, the next two require the **xintfrac** package, which deals with fractions. Then two examples with the **xintgcd** package, one with the **xintseries** package, and finally a computation with a float. Some inputs are simplified by the use of the **xintexpr** package.

```

52017095026186580166519903071841443223116967837696
```

---

<sup>5</sup>without entering into too much technical details, the source of this ‘wall’ is that when dealing with two long operands, when one wants to pick some digits from the second one, one has to jump above all digits constituting the first one, which can not be stored away: expandability forbids assignments to memory storage. One may envision some sophisticated schemes, dealing with this problem in less naive ways, trying to move big chunks of data higher up in the input stream and come back to it later, etc...; but each ‘better’ algorithm adds overhead for the smaller inputs. For example, I have another version of addition which is twice faster on inputs with 500 digits or more, but it is slightly less efficient for 50 digits or less. This ‘wall’ dissuaded me to look into implementing ‘intelligent’ multiplication which would be sub-quadratic in a model where storing and retrieving from memory do not cost much.

<sup>6</sup>I could, naturally, be proven wrong!

<sup>7</sup>The Lua $\text{\TeX}$  project possibly makes endeavours such as **xint** appear even more insane than they are, in truth.

```
\xintTypeSetEuclideanAlgorithm {22206980239027589097}{8169486210102119256}
22206980239027589097 = 2 \times 8169486210102119256 + 5868007818823350585
8169486210102119256 = 1 \times 5868007818823350585 + 2301478391278768671
5868007818823350585 = 2 \times 2301478391278768671 + 1265051036265813243
2301478391278768671 = 1 \times 1265051036265813243 + 1036427355012955428
```

---

<sup>8</sup>this example is computed tremendously faster than the other ones, but we had to limit the space taken by the output.

## 5 Some examples

```
1265051036265813243 = 1 × 1036427355012955428 + 228623681252857815
1036427355012955428 = 4 × 228623681252857815 + 121932630001524168
228623681252857815 = 1 × 121932630001524168 + 106691051251333647
121932630001524168 = 1 × 106691051251333647 + 15241578750190521
106691051251333647 = 7 × 15241578750190521 + 0
```

$\sum_{n=1}^{500} (4n^2 - 9)^{-2}$  with each term rounded to twelve digits, and the sum to nine digits:

```
\def\coeff #1%
{\xintiRound {12}{1/\xintiSqr{\the\numexpr 4*#1*#1-9\relax }[0]}}
\xintRound {9}{\xintiSeries {1}{500}{\coeff}{-12}}: 0.062366080
```

The complete series, extended to infinity, has value  $\frac{\pi^2}{144} - \frac{1}{162} = 0.062,366,079,945,836,595,346,844,45\dots$ <sup>9</sup> I also used (this is a lengthier computation than the one above) **xintseries** to evaluate the sum with 100,000 terms, obtaining 16 correct decimal digits for the complete sum. The coefficient macro must be redefined to avoid a `\numexpr` overflow, as `\numexpr` inputs must not exceed  $2^{31}-1$ ; my choice was:

```
\def\coeff #1%
{\xintiRound {22}{1/\xintiSqr{\xintiMul{\the\numexpr 2*#1-3\relax}
{\the\numexpr 2*#1+3\relax}}[0]}}
```

Computation of  $2^{999,999,999}$  with 24 significant figures:

```
\numprint{\xintFloatPow [24] {2}{999999999}} expands to:
2.306,488,000,584,534,696,558,06 × 10301,029,995
```

where the `\numprint` macro from the [eponym package](#) was used.

As an example of chaining package macros, let us consider the following code snippet within a file with filename `myfile.tex`:

```
\newwrite\outstream
\immediate\openout\outstream \jobname-out\relax
\immediate\write\outstream {\xintQuo{\xintPow{2}{1000}}{\xintFac{100}}}
% \immediate\closeout\outstream
```

The tex run creates a file `myfile-out.tex`, and then writes to it the quotient from the euclidean division of  $2^{1000}$  by  $100!$ . The number of digits is `\xintLen{\xintQuo{\xintPow{2}{1000}}{\xintFac{100}}}` which expands (in two steps) and tells us that  $[2^{1000}/100!]$  has 144 digits. This is not so many, let us print them here: 11481324 96415075054822783938725510662598055177841861728836634780658265418947 04737970419535798876630484358265060061503749531707793118627774829601.

For the sake of typesetting this documentation and not have big numbers extend into the margin and go beyond the page physical limits, I use these commands (not provided by the package):

```
\def\allowsplits #1{\ifx #1\relax \else #1\hskip .0pt plus 1pt \relax
\expandafter\allowsplits\fi}%
\def\printnumber #1{\expandafter\expandafter\expandafter
\allowssplits #1\relax }%
% Expands twice before printing.
```

---

<sup>9</sup>This number is typeset using the `numprint` package, with `\npthousandsep {,}\hskip 1pt plus .5pt minus .5pt`. But the breaking across lines works only in text mode. The number itself was (of course...) computed initially with `xint`, with 30 digits of  $\pi$  as input. See [how xint may compute  \$\pi\$  from scratch](#).

## 6 Origins of the package

The `\printnumber` macro is not part of the package and would need additional thinking for more general use.<sup>10</sup> It may be used as `\printnumber {\xintQuo{\xintPow {2}{1000}}{\xintFac{100}}}`, or as `\printnumber\mynumber` if the macro `\mynumber` was previously defined via an `\edef`, as for example:

```
\edef\mynumber {\xintQuo {\xintPow {2}{1000}}{\xintFac{100}}}  
or as \expandafter\printnumber\expandafter{\mynumber}, if the macro \mynumber  
is defined by a \newcommand or a \def; using seven rather than three \expandafter's in  
\printnumber would allow to use it directly as \printnumber\mynumber when \mynumber  
has been defined via a \def or \newcommand using a chain of package macros.
```

Just to show off (again), let's print 300 digits (after the decimal point) of the decimal expansion of  $0.7^{-25}$ :<sup>11</sup>

```
\np {\xinttheexpr trunc(.7^-25,300)\relax}\dots  
7,456.739,985,837,358,837,609,119,727,341,853,488,853,339,101,579,533,  
584,812,792,108,394,305,337,246,328,231,852,818,407,506,767,353,741,  
490,769,900,570,763,145,015,081,436,139,227,188,742,972,826,645,967,  
904,896,381,378,616,815,228,254,509,149,848,168,782,309,405,985,245,  
368,923,678,816,256,779,083,136,938,645,362,240,130,036,489,416,562,  
067,450,212,897,407,646,036,464,074,648,484,309,937,461,948,589...
```

This computation is with `\xinttheexpr` from package **xintexpr**, which allows to use standard infix notations and function names to access the package macros, such as here `trunc` which corresponds to the **xintfrac** macro `\xintTrunc`. The fraction  $0.7^{-25}$  is first evaluated *exactly*; for some more complex inputs, such as  $.7123045678952^{-243}$ , the exact evaluation before truncation would be expensive, and (assuming one needs twenty digits) one would rather use floating mode:

```
\xintDigits:=20; \np{\xintthefloatexpr .7123045678952^-243\relax}  
.7123045678952^-243 ≈ 6.342,022,117,488,416,127,3 × 1035
```

The exponent  $-243$  didn't have to be put inside parentheses, contrarily to what happens with some professional computational software.

To see more of **xint** in action, jump to the section 32 describing the commands of the **xintseries** package, especially as illustrated with the traditional computations of  $\pi$  and  $\log 2$ , or also see the computation of the convergents of  $e$  made with the **xintcfrac** package.

Almost all of the computational results interspersed through the documentation are not hard-coded in the source of the document but just written there using the package macros, and were selected to not impact too much the compilation time.

## 6 Origins of the package

Package **bigintcalc** by HEIKO OBERDIEK already provides expandable arithmetic operations on “big integers”, exceeding the TeX limits (of  $2^{31}-1$ ), so why another<sup>12</sup> one?

I got started on this in early March 2013, via a thread on the `c.t.tex` usenet group,

<sup>10</sup>as explained in a previous footnote, the **numprint** package may also be used, in text mode only (as the thousand separator seemingly ends up typeset in a `\hbox` when in math mode).

<sup>11</sup>the `\np` typesetting macro is from the **numprint** package.

<sup>12</sup>this section was written before the **xintfrac** package; the author is not aware of another package allowing expandable computations with arbitrarily big fractions.

where ULRICH D<sub>I</sub>EZ used the previously cited package together with a macro (`\ReverseOrder`) which I had contributed to another thread.<sup>13</sup> What I had learned in this other thread thanks to interaction with ULRICH D<sub>I</sub>EZ and GL on expandable manipulations of tokens motivated me to try my hands at addition and multiplication.

I wrote macros `\bigMul` and `\bigAdd` which I posted to the newsgroup; they appeared to work comparatively fast. These first versions did not use the  $\epsilon$ - $\text{\TeX}$  `\numexpr` primitive, they worked one digit at a time, having previously stored carry-arithmetic in 1200 macros.

I noticed that the `bigintcalc` package used `\numexpr` if available, but (as far as I could tell) not to do computations many digits at a time. Using `\numexpr` for one digit at a time for `\bigAdd` and `\bigMul` slowed them a tiny bit but avoided cluttering  $\text{\TeX}$  memory with the 1200 macros storing pre-computed digit arithmetic. I wondered if some speed could be gained by using `\numexpr` to do four digits at a time for elementary multiplications (as the maximal admissible number for `\numexpr` has ten digits).

The present package is the result of this initial questioning.

## 7 Expansions

By convention in this manual  $f$ -expansion (“full expansion” or “full first expansion”) is the process of expanding repeatedly the first token seen until hitting against something not further expandable like an unexpandable  $\text{\TeX}$ -primitive or an opening brace `{` or a character (inactive). For those familiar with  $\text{\LaTeX}3$  (which is not used by `xint`) this is what is called in its documentation full expansion. Technically, macro arguments in `xint` which are submitted to such a  $f$ -expansion are so via prefixing them with `\romannumeral-`0`. An explicit or implicit space token stops such an expansion and is gobbled.

Most of the package macros, and all those dealing with computations, are expandable in the strong sense that they expand to their final result via this  $f$ -expansion. Again copied from  $\text{\LaTeX}3$  documentation conventions, this will be signaled in the description of the

- ★ macro by a star in the margin. All<sup>14</sup> expandable macros of the `xint` packages completely expand in two steps.

Furthermore the macros dealing with computations, as well as many utilities from `xint-tools`, apply this process of  $f$ -expansion to their arguments. Again from  $\text{\LaTeX}3$ ’s conventions this will be signaled by a margin annotation. Some additional parsing which is done by most macros of `xint` is indicated with a variant; and the extended fraction parsing done by most macros of `xintfrac` has its own symbol. When the argument has a priori to obey the  $\text{\TeX}$  bound of 2147483647 it is systematically fed to a `\numexpr..\relax` hence the expansion is then a *complete* one, signaled with an  $x$  in the margin. This means not only complete expansion, but also that spaces are ignored, infix algebra is possible, count registers are allowed, etc...

- \* The `\xintApplyInline` and `\xintFor*` macros from `xinttools` apply a special iterated  $f$ -expansion, which gobbles spaces, to all those items which are found *unbraced* from left to right in the list argument; this is denoted specially as here in the margin. Some other macros such as `\xintSum` from `xintfrac` first do an  $f$ -expansion, then treat each found (braced or not) item (skipping spaces between such items) via the general fraction input

---

<sup>13</sup>the `\ReverseOrder` could be avoided in that circumstance, but it does play a crucial rôle here.

<sup>14</sup>except `\xintloop` and `\xintiloop`.

parsing, this is signaled as here in the margin where the signification of the \* is thus a bit different from the previous case.

- n*, resp. *o* A few macros from **xinttools** do not expand, or expand only once their argument. This is also signaled in the margin with notations à la L<sup>A</sup>T<sub>E</sub>X3.

As the computations are done by *f*-expandable macros which *f*-expand their argument they may be chained up to arbitrary depths and still produce expandable macros.

Conversely, wherever the package expects on input a “big” integers, or a “fraction”, *f*-expansion of the argument *must result in a complete expansion* for this argument to be acceptable.<sup>15</sup> The main exception is inside `\xintexpr...\\relax` where everything will be expanded from left to right, completely.

Summary of important expansion aspects:

1. the macros *f*-expand their arguments, this means that they expand the first token seen (for each argument), then expand, etc..., until something un-expandable such as a digit or a brace is hit against. This example

```
\def\x{98765}\def\y{43210}\xintAdd {\x}{\y}
```

is *not* a legal construct, as the `\y` will remain untouched by expansion and not get converted into the digits which are expected by the sub-routines of `\xintAdd`. It is a `\numexpr` which will expand it and an arithmetic overflow will arise as 9876543210 exceeds the T<sub>E</sub>X bounds.

With `\xinttheexpr` one could write `\xinttheexpr \x+\x\y\relax`, or `\xintAdd \x{\xinttheexpr\x\y\relax}`.

2. using `\if...\\fi` constructs *inside* the package macro arguments requires suitably mastering T<sub>E</sub>Xniques (`\expandafter`'s and/or swapping techniques) to ensure that the *f*-expansion will indeed absorb the `\else` or closing `\fi`, else some error will arise in further processing. Therefore it is highly recommended to use the package provided conditionals such as `\xintifEq`, `\xintifGt`, `\xintifSgn`, `\xintifOdd...`, or, for L<sup>A</sup>T<sub>E</sub>X users and when dealing with short integers the `etoolbox`<sup>16</sup> expandable conditionals (for small integers only) such as `\ifnumequal`, `\ifnumgreater`, .... Use of *non-expandable* things such as `\ifthenelse` is impossible inside the arguments of **xint** macros.

One can use naive `\if..\\fi` things inside an `\xinttheexpr`-ession and cousins, as long as the test is expandable, for example

```
\xinttheexpr\ifnum3>2 143\else 33\fi 0^2\relax→2044900=1430^2
```

3. after the definition `\def\x {12}`, one can not use `-\\x` as input to one of the package macros: the *f*-expansion will act only on the minus sign, hence do nothing. The only way is to use the `\xintOpp` macro, or perhaps here rather `\xintiOpp` which does maintains integer format on output, as they replace a number with its opposite.

Again, this is otherwise inside an `\xinttheexpr`-ession or `\xintthefloatexpr`-ession. There, the minus sign may prefix macros which will expand to numbers (or parentheses etc...)

---

<sup>15</sup>this is not quite as stringent as claimed here, see section 11 for more details.

<sup>16</sup><http://www.ctan.org/pkg/etoolbox>

4. With the definition

```
\def\AplusBC #1#2#3{\xintAdd {#1}{\xintMul {#2}{#3}}}
```

one obtains an expandable macro producing the expected result, not in two, but rather in three steps: a first expansion is consumed by the macro expanding to its definition. As the package macros expand their arguments until no more is possible (regarding what comes first), this `\AplusBC` may be used inside them: `\xintAdd {\AplusBC {1}{2}{3}}{4}` does work and returns `11/1[0]`.

If, for some reason, it is important to create a macro expanding in two steps to its final value, one may either do:

```
\def\AplusBC #1#2#3{\romannumeral-‘0\xintAdd {#1}{\xintMul {#2}{#3}}}
or use the lowercase form of \xintAdd:
```

```
\def\AplusBC #1#2#3{\romannumeral0\xintadd {#1}{\xintMul {#2}{#3}}}
```

and then `\AplusBC` will share the same properties as do the other `xint` ‘primitive’ macros.

The `\romannumeral0` and `\romannumeral-‘0` things above look like an invitation to hacker’s territory; if it is not important that the macro expands in two steps only, there is no reason to follow these guidelines. Just chain arbitrarily the package macros, and the new ones will be completely expandable and usable one within the other.

Since release 1.07 the `\xintNewExpr` command automatizes the creation of such expandable macros:

```
\xintNewExpr\AplusBC[3]{#1+#2*#3}
```

creates the `\AplusBC` macro doing the above and expanding in two expansion steps.

## 8 Input formats

The core bundle constituents are `xint`, `xintfrac`, `xintexpr`, each one loading its predecessor. The base constituent `xint` only handles (big) integers, and `xintfrac` additionally manages decimal numbers, numbers in scientific notation, and fractions. Both load `xint-tools` which provides utilities not directly related to big numbers.

The package macros first *f*-expand their arguments: the first token of the argument is repeatedly expanded until no more is possible.

For those arguments which are constrained to obey the T<sub>E</sub>X bounds on numbers, they are systematically inserted inside a `\numexpr... \relax` expression, hence the expansion is then a complete one.

The allowed input formats for ‘long numbers’ and ‘fractions’ are:

*f*

1. the strict format is for some macros of `xint` which only *f*-expand their arguments. After this *f*-expansion the input should be a string of digits, optionally preceded by a unique minus sign. The first digit can be zero only if the number is zero. A plus sign is not accepted. `-0` is not legal in the strict format.
2. the macro `\xintNum` normalizes into strict format an input having arbitrarily many minus and plus signs, followed by a string of zeros, then digits:

```
\xintNum {-----00000000009876543210}=-9876543210
```

Num  
*f*

The extended integer format is thus for the arithmetic macros of `xint` which automatically parse their arguments via this `\xintNum`.

`Frac`

3. the fraction format is what is expected by the macros of **xintfrac**: a fraction is constituted of a numerator A and optionally a denominator B, separated by a forward slash / and A and B may be macros which will be automatically given to `\xintNum`. Each of A and B may be decimal numbers (the decimal mark must be a .). Here is an example:<sup>17</sup>

```
\xintAdd {+-0367.8920280/-+278.289287}{-109.2882/+270.12898}
```

Incidentally this evaluates to

```
=-129792033529284840/7517400124223726[-1]
=-6489601676464242/3758700062111863 (irreducible)
=-1.72655481129771093694248704898677881556360055242806...
```

where the second line was produced with `\xintIrr` and the next with `\xintTrunc{50}` to get fifty digits of the decimal expansion following the decimal mark. Scientific notation is accepted for both numerator and denominator of a fraction, and is produced on output by `\xintFloat`:

```
\xintAdd{10.1e1}{101.010e3}=101111/1[0]
\xintFloatAdd{10.1e1}{101.010e3}=1.011110000000000e5
\xintFloat{\xintiPow{2}{100}}=1.267650600228229e30
```

Produced fractions with a denominator equal to one are nevertheless generally printed as fraction. In math mode `\xintFrac` will remove such dummy denominators, and in inline text mode one has `\xintPRaw` with the similar effect.

```
\xintPRaw{\xintAdd{10.1e1}{101.010e3}}=101111
\xintRaw{1.234e5/6.789e3}=1234/6789[2]
\xintFloat[24]{1/66049}=1.51402746445820527184363e-5
```

4. the **expression format** is for inclusion in an `\xintexpr...\\relax`, it uses infix notations, function names, complete expansion, and is described in its devoted section ([section 24](#)).

Even with **xintfrac** loaded, some macros by their nature can not accept fractions on input. Those parsing their inputs through `\xintNum` will accept a fraction reducing to an integer. For example `\xintQuo{100/2}{12/3}` works, because its arguments are, after simplification, integers. In this documentation, I often say “numbers or fractions”, although at times the word “numbers” by itself may also include “fractions”; and “decimal numbers” are counted among “fractions”.

A number can start directly with a decimal point:

```
\xintPow{- .3/.7}{11}=-177147/1977326743[0]
\xinttheexpr (- .3/.7)^11\\relax=-177147/1977326743[0]
```

It is also licit to use `\A/\B` as input if each of `\A` and `\B` expands (in the sense previously described) to a “decimal number” as exemplified above by the numerators and denominators (thus, possibly with a ‘scientific’ exponent part, with a lowercase ‘e’). Or one may have just one macro `\C` which expands to such a “fraction with optional decimal points”, or mixed things such as `\A 245/7.77`, where the numerator will be the concatenation of the expansion of `\A` and 245. But, as explained already `123\A` is a no-go, *except inside an \xintexpr-expression!*

The scientific notation is necessarily (except in `\xintexpr..\\relax`) with a lowercase e. It may appear both at the numerator and at the denominator of a fraction.

---

<sup>17</sup>the square brackets one sees in various outputs are explained near the end of this section.

`\xintRaw {+--1253.2782e+--3/-0087.123e--5}=-12532782/87123[7]`

**Num f** Arithmetic macros of **xint** which parse their arguments automatically through **\xint-Num** are signaled by a special symbol in the margin. This symbol also means that these arguments may contain to some extent infix algebra with count registers, see the section [Use of count registers](#).

**Frac f** With **xintfrac** loaded the symbol  $\frac{N}{f}$  means that a fraction is accepted if it is a whole number in disguise; and for macros accepting the full fraction format with no restriction there is the corresponding symbol in the margin.

Summary of the input formats for the bundle macros dealing with numbers (except `\xintexpr..\relax`):

- num x**
  1. ‘short’ integers, *i.e.* less than (or equal to) in absolute value 2,147,483,647. I will refer to this as the ‘**T<sub>E</sub>X**’ or ‘`\numexpr`’ limit. This is the case for arguments which serve to count or index something. It is also the case for the exponent in the power function and for the argument to the factorial function.<sup>18</sup> When the argument exceeds the **T<sub>E</sub>X** bound (either positively or negatively), an error will originate from a `\numexpr` expression and it may sometimes be followed by a more specific error ‘message’ from a package macro.
  2. ‘long’ integers in strict format: only one optional minus sign, anything starting with zero is treated as zero. Some macros of **xint** require this format, but most accept the extended format described in the next item; they may then have a ‘strict’ variant for optimizing purposes with a ‘`ii`’ in their names, this variant remains available even with **xintfrac** loaded. A count register can serve as argument of such a macro only if prefixed by `\the` or `\number`.
- Num f**
  3. ‘long’ integers automatically parsed by **\xintNum**, they may have leading signs followed by leading zeros, and they may be count registers with no need of being prefixed by `\the` or `\number`.<sup>19</sup> The number of digits must (as in the strict format) be less than 2,147,483,647.
  4. ‘fractions’: they become available after having loaded the **xintfrac** package. A fraction has a numerator, a forward slash and then a denominator. Both can use scientific notation (with a lowercase e) and the dot as decimal mark. No separator for thousands. Except within `\xintexpr`-essions, spaces should be avoided.

Regarding fractions, the **xintfrac** macros generally output in  $A/B[n]$  format, representing the fraction  $A/B \times 10^n$ .

This format with a trailing  $[n]$  (possibly,  $n=0$ ) is accepted on input but it presupposes that the numerator and denominator  $A$  and  $B$  are in the strict integer format described above. So  $16000/289072[17]$  or  $3[-4]$  are authorized and it is even possible to use `\A/\B[17]` if `\A` expands to  $16000$  and `\B` to  $289072$ , or `\A` if `\A` expands to  $3[-4]$ . However, NEITHER the numerator NOR the denominator may then have a decimal point. And, for this format,

<sup>18</sup>the bound has even been lowered for them but the float power function limits the exponent only to the **T<sub>E</sub>X** bound, and has a variant with no imposed limit on the exponent; but the result of the computation must in all cases be representable with a power of ten exponent obeying the **T<sub>E</sub>X** bound.

<sup>19</sup>A **L<sub>A</sub>T<sub>E</sub>X** `\value{countername}` is accepted, if there is nothing else, especially before, in the macro argument.

## 9 Output formats

ONLY the numerator may carry a UNIQUE minus sign (and no superfluous leading zeros; and NO plus sign).

This format with a power of ten represented by a number within square brackets is the output format used by (almost all) **xintfrac** macros dealing with fractions. It is allowed for user input but the parsing is minimal and it is mandatory to follow the above rules. This reduced flexibility, compared to the format without the square brackets, allows chaining package macros without too much speed impact, as they always output computation results in the A/B[n] form.

All computations done by **xintfrac** on fractions are exact. Inputs containing decimal points or scientific parts do not make the package switch to a ‘floating-point’ mode. The inputs, however long, are always converted into exact internal representations.

Floating point evaluations are done with special macros containing ‘Float’ in their names, or inside \xintthefloatexpr-essions.

Generally speaking, there should be no spaces among the digits in the inputs (in arguments to the package macros). Although most would be harmless in most macros, there are some cases where spaces could break havoc. So the best is to avoid them entirely.

This is entirely otherwise inside an \xintexpr-ession, where spaces are ignored (except when they occur inside arguments to some some macros, thus escaping the \xintexpr parser). See the [documentation](#).

## 9 Output formats

With package **xintfrac** loaded, the routines `\xintAdd`, `\xintSub`, `\xintMul`, `\xintPow`, `\xintSum`, `\xintPrd` are modified to allow fractions on input<sup>20 21 22 23</sup> and produce on output a fractional number  $f=A/B[n]$  where A and B are integers, with B positive, and n is a “short” integer (*i.e* less in absolute value than  $2^{31}-9$ ). This represents  $(A/B)$  times  $10^n$ . The fraction f may be, and generally is, reducible, and A and B may well end up with zeros (*i.e.* n does not contain all powers of 10). Conversely, this format is accepted on input (and is parsed more quickly than fractions containing decimal points; the input may be a number without denominator).<sup>24</sup>

<sup>20</sup>the power function does not accept a fractional exponent. Or rather, does not expect, and errors will result if one is provided.

<sup>21</sup>macros `\xintiAdd`, `\xintiSub`, `\xintiMul`, `\xintiPow`, are the original ones dealing only with integers. They are available as synonyms, also when **xintfrac** is not loaded. With **xintfrac** loaded they accept on input also fractions, if these fractions reduce to integers, and the output format is the original **xint**’s one. The macros `\xintiiAdd`, `\xintiiSub`, `\xintiiMul`, `\xintiiPow`, `\xintiiSum`, `\xintiiPrd` are strictly integer-only: they skip the overhead of parsing their arguments via `\xintNum`.

<sup>22</sup>also `\xintCmp`, `\xintSgn`, `\xintGeq`, `\xintOpp`, `\xintAbs`, `\xintMax`, `\xintMin` are extended to fractions; and the last four have the integer-only variants `\xintiOpp`, `\xintiAbs`, `\xintiMax`, `\xintiMin`.

<sup>23</sup>and `\xintFac`, `\xintQuo`, `\xintRem`, `\xintDivision`, `\xintFDg`, `\xintLDg`, `\xintOdd`, `\xintMON`, `\xintMMON` all accept a fractional input as long as it reduces to an integer.

<sup>24</sup>at each stage of the computations, the sum of n and the length of A, or of the absolute value of n and the length of B, must be kept less than  $2^{31}-9$ .

## 9 Output formats

Thus loading **xintfrac** not only relaxes the format of the inputs; it also modifies the format of the outputs: except when a fraction is filtered on output by **\xintIrr** or **\xintRawWithZeros**, or **\xintPRaw**, or by the truncation or rounding macros, or is given as argument in math mode to **\xintFrac**, the output format is normally of the  $A/B[n]$  form (which stands for  $(A/B) \times 10^n$ ). The A and B may end in zeros (*i.e.*, n does not represent all powers of ten), and will generally have a common factor. The denominator B is always strictly positive.

A macro **\xintFrac** is provided for the typesetting (math-mode only) of such a ‘raw’ output. The command **\xintFrac** is not accepted as input to the package macros, it is for typesetting only (in math mode).

The macro **\xintRaw** prints the fraction directly from its internal representation in  $A/B[n]$  form. The macro **\xintPRaw** does the same but without printing the [n] if  $n=0$  and without printing /1 if  $B=1$ .

To convert the trailing [n] into explicit zeros either at the numerator or the denominator, use **\xintRawWithZeros**. In both cases the B is printed even if it has value 1. Conversely (sort of), the macro **\xintREZ** puts all powers of ten into the [n] (REZ stands for remove zeros). Here also, the B is printed even if it has value 1.

The macro **\xintIrr** reduces the fraction to its irreducible form C/D (without a trailing [0]), and it prints the D even if D=1.

The macro **\xintNum** from package **xint** is extended: it now does like **\xintIrr**, raises an error if the fraction did not reduce to an integer, and outputs the numerator. This macro should be used when one knows that necessarily the result of a computation is an integer, and one wants to get rid of its denominator /1 which would be left by **\xintIrr** (or one can use **\xintPRaw** on top of **\xintIrr**).

The macro **\xintTrunc{N}{f}** prints<sup>25</sup> the decimal expansion of f with N digits after the decimal point.<sup>26</sup> Currently, it does not verify that N is non-negative and strange things could happen with a negative N. A negative f is no problem, needless to say. When the original fraction is negative and its truncation has only zeros, it is printed as -0.0...0, with N zeros following the decimal point:

```
\xintTrunc {5}{\xintPow {-13}{-9}}=-0.00000
\xintTrunc {20}{\xintPow {-13}{-9}}=-0.0000000009429959537
```

The output always contains a decimal point (even for  $N=0$ ) followed by N digits, except when the original fraction was zero. In that case the output is 0, with no decimal point.

```
\xintTrunc {10}{\xintSum {{1/2}{1/3}{1/5}{-31/30}}} = 0
```

The macro **\xintiTrunc{N}{f}** is like **\xintTrunc{N}{f}** followed by multiplication by  $10^N$ . Thus, it outputs an integer in a format acceptable by the integer-only macros. To get the integer part of the decimal expansion of f, use **\xintiTrunc{0}{f}**:

```
\xintiTrunc {0}{\xintPow {1.01}{100}} = 2
\xintiTrunc {0}{\xintPow {0.123}{-10}} = 1261679032
```

---

<sup>25</sup>‘prints’ does not at all mean that this macro is designed for typesetting; I am just using the verb here in analogy to the effect of the functioning of a computing software in console mode. The package does not provide any ‘printing’ facility, besides its rudimentary **\xintFrac** and **\xintFwOver** math-mode only macros. To deal with really long numbers, some macros are necessary as T<sub>E</sub>X by default will print a long number on a single line extending beyond the page limits. The **\printnumber** command used in this documentation is just one way to address this problem, some other method should be used if it is important that digits occupy the same width always.

<sup>26</sup>the current release does not provide a macro to get the period of the decimal expansion.

See also the documentations of `\xintRound`, `\xintiRound` and `\xintFloat`.

The `\xintiAdd`, `\xintiSub`, `\xintiMul`, `\xintiPow`, and some others accept fractions on input under the condition that they are (big) integers in disguise and then output a (possibly big) integer, without fraction slash nor trailing [n].

The `\xintiiAdd`, `\xintiiSub`, `\xintiiMul`, `\xintiiPow`, and some others with ‘ii’ in their names accept on input only integers in strict format (skipping the overhead of the `\xintNum` parsing) and output naturally a (possibly big) integer, without fraction slash nor trailing [n].

## 10 Multiple outputs

Some macros have an output consisting of more than one number or fraction, each one is then returned within braces. Examples of multiple-output macros are `\xintDivision` which gives first the quotient and then the remainder of euclidean division, `\xintBezout` from the `xintgcd` package which outputs five numbers, `\xintFtoCv` from the `xintcfrac` package which returns the list of the convergents of a fraction, ... [section 14](#) and [section 15](#) mention utilities, expandable or not, to cope with such outputs.

Another type of multiple outputs is when using commas inside `\xintexpr..\relax`:

`\xinttheiexpr 10!,2^20,lcm(1000,725)\relax` → 3628800,1048576,29000

## 11 Use of count registers

Inside `\xintexpr..\relax` and its variants, a count register or count control sequence is automatically unpacked using `\number`, with tacit multiplication: `1.23\counta` is like `1.23*\counta`. We use `\number` which is slightly slower on count registers than `\the`, because the parser does not discriminate between a count and a dimen control sequence. And `\the` on a dimen variable produces only an approximate representation in points of the internal value in sp units. See the next section for more.

Regarding now the package macros, there is first the case of an argument said in the documentation to have to obey the `\TeX` bound: this means that it is fed to a `\numexpr...\relax`, hence it is submitted to a *complete expansion* which must deliver an integer, and count registers and even algebraic expressions with them like `\mycountA+\mycountB*17-\mycountC/12+\mycountD` are admissible arguments (the slash stands here for the rounded integer division done by `\numexpr`). This applies in particular to the number of digits to truncate or round with, to the indices of a series partial sum, ...

The macros dealing with long numbers or fractions allow (when not limited to the ‘strict integer’ format on input) *to some extent* the direct use of count registers and even infix algebra with them inside their arguments: a count register `\mycountA` or `\count 255` is admissible as numerator or also as denominator, with no need to be prefixed by `\the` or `\number`. It is possible to have as argument an algebraic expression as would be acceptable by a `\numexpr...\relax`, under this condition: *each of the numerator and denominator is expressed with at most eight tokens*.<sup>27</sup> The slash for rounded division in a `\numexpr` should be written with braces `{/}` to not be confused with the `xintfrac` delimiter

IMPORTANT!

---

<sup>27</sup>Attention! there is no problem with a `\TeX \value{countername}` if it comes first, but if it comes later in the input it will not get expanded, and braces around the name will be removed and chaos will ensues inside a `\numexpr`. One should enclose the whole input in `\the\numexpr...\relax` in such cases.

between numerator and denominator (braces will be removed internally). Example: `\mycountA+\mycountB{/}17/1+\mycountA*\mycountB`, or `\count 0+\count 2{/}17/1+\count 0*\count 2`, but in the latter case the numerator has the maximal allowed number of tokens (the braced slash counts for only one).

```
\cnta 10 \cntb 35 \xintRaw {\cnta+\cntb{/}17/1+\cnta*\cntb}->12/351[0]
```

For longer algebraic expressions using count registers, there are two possibilities:

1. encompass each of the numerator and denominator in `\the\numexpr...` `\relax`,
2. encompass each of the numerator and denominator in `\numexpr ... \relax`.

```
\cnta 100 \cntb 10 \cntc 1
\xintPRaw {\numexpr {\cnta*\cnta+\cntb*\cntb+\cntc*\cntc+
2*\cnta*\cntb+2*\cnta*\cntc+2*\cntb*\cntc}\relax%
\numexpr {\cnta*\cnta+\cntb*\cntb+\cntc*\cntc}\relax }
12321/10101
```

The braces would not be accepted as regular `\numexpr`-syntax: and indeed, they are removed at some point in the processing.

## 12 Dimensions

$\langle\dimen\rangle$  variables can be converted into (short) integers suitable for the **xint** macros by prefixing them with `\number`. This transforms a dimension into an explicit short integer which is its value in terms of the `sp` unit (1/65536 pt). When `\number` is applied to a  $\langle\glue\rangle$  variable, the stretch and shrink components are lost.

For L<sup>A</sup>T<sub>E</sub>X users: a length is a  $\langle\glue\rangle$  variable, prefixing a length command defined by `\newlength` with `\number` will thus discard the plus and minus glue components and return the dimension component as described above, and usable in the **xint** bundle macros.

New!

- This conversion is done automatically inside an `\xintexpr`-essions, with tacit multiplication implied if prefixed by some (integral or decimal) number.

One may thus compute areas or volumes with no limitations, in units of `sp^2` respectively `sp^3`, do arithmetic with them, compare them, etc..., and possibly express some final result back in another unit, with the suitable conversion factor and a rounding to a given number of decimal places.

A [table of dimensions](#) illustrates that the internal values used by T<sub>E</sub>X do not correspond always to the closest rounding. For example a millimeter exact value in terms of `sp` units is  $72.27/10/2.54*65536=186467.981\dots$  and T<sub>E</sub>X uses internally `186467sp` (it thus appears that T<sub>E</sub>X truncates to get an integral multiple of the `sp` unit).

There is something quite amusing with the Didot point. According to the T<sub>E</sub>XBook,  $1157\text{ dd}=1238\text{ pt}$ . The actual internal value of `1 dd` in T<sub>E</sub>X is `70124 sp`. We can use **xintcfrac** to display the list of centered convergents of the fraction  $70124/65536$ :

```
\xintListWithSep{, }{\xintFtoCCv{70124/65536}}
1/1, 15/14, 61/57, 107/100, 1452/1357, 17531/16384, and we don't find 1238/1157
therein, but another approximant 1452/1357!
```

And indeed multiplying `70124/65536` by `1157`, and respectively `1357`, we find the approximations (wait for more, later):

“`1157 dd`=`1237.998474121093...pt`

Unit	definition	Exact value in sp units	$\text{\TeX}'s$ value in sp units	Relative error
<b>cm</b>	0.01 m	$236814336/127 = 1864679.811\dots$	1864679	-0.0000%

<b>pc</b>	12 pt	$786432/1 = 786432.000\dots$	786432	0%
<b>pt</b>	1/72.27 in	$65536/1 = 65536.000\dots$	65536	0%
<b>bp</b>	1/72 in	$1644544/25 = 65781.760\dots$	65781	-0.0012%
3bp	1/24 in	$4933632/25 = 197345.280\dots$	197345	-0.0001%
12bp	1/2 in	$19734528/25 = 789381.120\dots$	789381	-0.0000%
72bp	3 in	$118407168/25 = 4736286.720\dots$	4736286	-0.0000%
<b>dd</b>	1238/1157 pt	$81133568/1157 = 70124.086\dots$	70124	-0.0001%
11dd	$11*1238/1157$ pt	$892469248/1157 = 771364.950\dots$	771364	-0.0001%
12dd	$12*1238/1157$ pt	$973602816/1157 = 841489.037\dots$	841489	-0.0000%
<b>sp</b>	1/65536 pt	$1/1 = 1.000\dots$	1	0%

**TeX dimensions**

“1357 dd”=1451.999938964843... pt

and we seemingly discover that 1357 dd=1452 pt is *far more accurate* than the  $\text{\TeX}$ Book formula 1157 dd=1238 pt ! The formula to compute N dd was

```
\xinttheexpr trunc(N\dimexpr 1dd\relax/\dimexpr 1pt\relax,12)\relax}
```

What's the catch? The catch is that  $\text{\TeX}$  does not compute 1157 dd like we just did:

```
1157 dd=\number\dimexpr 1157dd\relax/65536=1238.000000000000...pt
```

```
1357 dd=\number\dimexpr 1357dd\relax/65536=1452.001724243164...pt
```

We thus discover that  $\text{\TeX}$  (or rather here, e- $\text{\TeX}$ , but one can check that this works the same in  $\text{\TeX}82$ ), uses indeed 1238/1157 as a conversion factor, and necessarily intermediate computations are done with more precision than is possible with only integers less than  $2^{31}$  (or  $2^{30}$  for dimensions). Hence the 1452/1357 ratio is irrelevant, a misleading artefact of the necessary rounding (or, as we see, truncating) for one bp as an integral number of sp's.

Let us now use `\xinttheexpr` to compute the value of the Didot point in millimeters, if the above rule is exactly verified:

```
\xinttheexpr trunc(1238/1157*25.4/72.27,12)\relax=0.376065027442...mm
```

This fits very well with the possible values of the Didot point as listed in the [Wikipedia Article](#). The value 0.376065 mm is said to be the *the traditional value in European printers' offices*. So the 1157 dd=1238 pt rule refers to this Didot point, or more precisely to the *conversion factor* to be used between this Didot and  $\text{\TeX}$  points.

The actual value in millimeters of exactly one Didot point as implemented in  $\text{\TeX}$  is

```
\xinttheexpr trunc(\dimexpr 1dd\relax/65536/72.27*25.4,12)\relax  
=0.376064563929...mm
```

The difference of circa 5Å is arguably tiny!

By the way the *European printers' offices* (dixit Wikipedia) *Didot* is thus exactly `\xinttheexpr reduce(.376065/(25.4/72.27))\relax=543564351/508000000 pt` and the centered convergents of this fraction are 1/1, 15/14, 61/57, 107/100, 1238/1157, 11249/10513, 23736/22183, 296081/276709, 615898/575601, 11382245/10637527, 22148592/20699453, 188570981/176233151, 543564351/508000000. We do recover the 1238/1157 therein!

## 13 \ifcase, \ifnum, ... constructs

When using things such as `\ifcase \xintSgn{\A}` one has to make sure to leave a space after the closing brace for  $\text{\TeX}$  to stop its scanning for a number: once  $\text{\TeX}$  has finished expanding `\xintSgn{\A}` and has so far obtained either 1, 0, or -1, a space (or something ‘unexpandable’) must stop it looking for more digits. Using `\ifcase\xintSgn\A` without the braces is very dangerous, because the blanks (including the end of line) following `\A` will be skipped and not serve to stop the number which `\ifcase` is looking for. With `\def\A{1}`:

```
\ifcase \xintSgn\A      0\or OK\else ERROR\fi    ---> gives ERROR
\ifcase \xintSgn\A\space 0\or OK\else ERROR\fi    ---> gives OK
\ifcase \xintSgn{\A}     0\or OK\else ERROR\fi    ---> gives OK
```

In order to use successfully `\if... \fi` constructions either as arguments to the **xint** bundle expandable macros, or when building up a completely expandable macro of one’s own, one needs some  $\text{\TeX}$ nical expertise (see also item 2 on page 11).

It is thus much to be recommended to opt rather for already existing expandable branching macros, such as the ones which are provided by **xint**: `\xintSgnFork`, `\xintifSgn`, `\xintifZero`, `\xintifOne`, `\xintifNotZero`, `\xintifTrueAelseB`, `\xintifCmp`, `\xintifGt`, `\xintifLt`, `\xintifEq`, `\xintifOdd`, and `\xintifInt`. See their respective documentations. All these conditionals always have either two or three branches, and empty brace pairs {} for unused branches should not be forgotten.

If these tests are to be applied to standard  $\text{\TeX}$  short integers, it is more efficient to use (under  $\text{\LaTeX}$ ) the equivalent conditional tests from the `etoolbox`<sup>28</sup> package.

## 14 Assignments

It might not be necessary to maintain at all times complete expandability. For example why not allow oneself the two definitions `\edef\A {\xintQuo{100}{3}}` and `\edef\B {\xintRem {100}{3}}`. A special syntax is provided to make these things more efficient, as the package provides `\xintDivision` which computes both quotient and remainder at the same time:

```
\xintAssign\xintDivision{100}{3}\to\A\B
\xintAssign\xintDivision{\xintiPow {2}{1000}}{\xintFac{100}}\to\A\B
gives \meaning\A: macro:->11481324964150750548227839387255106625980551
77841861728836634780658265418947047379704195357988766304843582650600
61503749531707793118627774829601 and \meaning\B: macro:->5493629452133
98322513812878622391280734105004984760505953218996123132766490228838
81328787024445820751296031520410548049646250831385676526243868372056
68069376.
```

Another example (which uses a macro from the **xintgcd** package):

```
\xintAssign\xintBezout{357}{323}\to\A\B\U\V\D
```

is equivalent to setting `\A` to 357, `\B` to 323, `\U` to -9, `\V` to -10, and `\D` to 17. And indeed  $(-9) \times 357 - (-10) \times 323 = 17$  is a Bezout Identity.

Thus, what `\xintAssign` does is to first apply an *f-expansion* to what comes next; it then defines one after the other (using `\edef`; an optional argument allows to modify the

<sup>28</sup><http://www.ctan.org/pkg/etoolbox>

expansion type, see subsection 26.23 for details), the macros found after \to to correspond to the successive braced contents (or single tokens) located prior to \to.

\xintAssign\xintBezout{3570902836026}{200467139463}\to\A\B\U\V\D gives then \U: macro:->5812117166, \V: macro:->103530711951 and \D=3.

In situations when one does not know in advance the number of items, one has \xintAssignArray or its synonym \xintDigitsOf:

\xintDigitsOf\xintiPow{2}{100}\to\DIGITS

This defines \DIGITS to be macro with one parameter, \DIGITS{0} gives the size N of the array and \DIGITS{n}, for n from 1 to N then gives the nth element of the array, here the nth digit of  $2^{100}$ , from the most significant to the least significant. As usual, the generated macro \DIGITS is completely expandable (in two steps). As it wouldn't make much sense to allow indices exceeding the T<sub>E</sub>X bounds, the macros created by \xintAssignArray put their argument inside a \numexpr, so it is completely expanded and may be a count register, not necessarily prefixed by \the or \number. Consider the following code snippet:

```
\newcount\cnta
\newcount\cntb
\begingroup
\xintDigitsOf\xintiPow{2}{100}\to\DIGITS
\cnta = 1
\cntb = 0
\loop
\advance \cntb \xintiSqr{\DIGITS{\cnta}}
\ifnum \cnta < \DIGITS{0}
\advance\cnta 1
\repeat

|2^{100}| (=xintiPow {2}{100}) has \DIGITS{0} digits and the sum of
their squares is \the\cntb. These digits are, from the least to
the most significant: \cnta = \DIGITS{0}
\loop \DIGITS{\cnta}\ifnum \cnta > 1 \advance\cnta -1 , \repeat.
\endgroup
```

$2^{100}$  ( $=1267650600228229401496703205376$ ) has 31 digits and the sum of their squares is 679. These digits are, from the least to the most significant: 6, 7, 3, 5, 0, 2, 3, 0, 7, 6, 9, 4, 1, 0, 4, 9, 2, 2, 8, 2, 2, 0, 0, 6, 0, 5, 6, 7, 6, 2, 1.

Warning: \xintAssign, \xintAssignArray and \xintDigitsOf do not do any check on whether the macros they define are already defined.

In the example above, we deliberately broke all rules of complete expandability, but had we wanted to compute the sum of the digits, not the sum of the squares, we could just have written: \xintiSum{\xintiPow{2}{100}}=115. Indeed, \xintiSum is usually used on braced items as in

\xintiSum{{123}{-345}{\xintFac{7}}{\xintiOpp{\xintRem{3347}{591}}}}=4426 but in the previous example each digit of  $2^{100}$  was treated as one item due to the rules of T<sub>E</sub>X for parsing macro arguments.

Note: {-\xintRem{3347}{591}} would not be a valid input, because the expansion will apply only to the minus sign and leave unaffected the \xintRem. So we used \xintiOpp which replaces a number with its opposite.

## 15 Utilities for expandable manipulations

The package now has more utilities to deal expandably with ‘lists of things’, which were treated un-expandably in the previous section with `\xintAssign` and `\xintAssignArray`: `\xintReverseOrder` and `\xintLength` since the first release, `\xintApply` and `\xintListWithSep` since 1.04, `\xintRevWithBraces`, `\xintCSVtoList`, `\xintNthElt` since 1.06, `\xintApplyUnbraced`, since 1.06b, `\xintloop` and `\xintiloop` since 1.09g.<sup>29</sup>

As an example the following code uses only expandable operations:

```
|2^{100}| (= \xintiPow {2}{100}) has \xintLen{\xintiPow {2}{100}} digits  
and the sum of their squares is  
\xintiiSum{\xintApply {\xintiSqr}{\xintiPow {2}{100}}}.
```

These digits are, from the least to the most significant:  
`\xintListWithSep {, }{\xintRev{\xintiPow {2}{100}}}`. The thirteenth most significant digit is `\xintNthElt{13}{\xintiPow {2}{100}}`. The seventh least significant one is `\xintNthElt{7}{\xintRev{\xintiPow {2}{100}}}`.

$2^{100}$  ( $= 1267650600228229401496703205376$ ) has 31 digits and the sum of their squares is 679. These digits are, from the least to the most significant: 6, 7, 3, 5, 0, 2, 3, 0, 7, 6, 9, 4, 1, 0, 4, 9, 2, 2, 8, 2, 2, 0, 0, 6, 0, 5, 6, 7, 6, 2, 1. The thirteenth most significant digit is 8. The seventh least significant one is 3.

It would be nicer to do `\edef\z{\xintiPow {2}{100}}`, and then use `\z` in place of `\xintiPow {2}{100}` everywhere as this would spare the CPU some repetitions.

Expandably computing primes is done in [subsection 26.10](#).

## 16 A new kind of for loop

As part of the `utilities` coming with the `xinttools` package, there is a new kind of for loop, `\xintFor`. Check it out ([subsection 26.17](#)).

## 17 A new kind of expandable loop

Also included in `xinttools`, `\xintloop` is an expandable loop giving access to an iteration index, without using count registers which would break expandability. Check it out ([subsection 26.13](#)).

## 18 Exceptions (error messages)

In situations such as division by zero, the package will insert in the TeX processing an undefined control sequence (we copy this method from the `bigintcalc` package). This will trigger the writing to the log of a message signaling an undefined control sequence. The name of the control sequence is the message. The error is raised *before* the end of the expansion so as to not disturb further processing of the token stream, after completion of the operation. Generally the problematic operation will output a zero. Possible such error message control sequences:

`\xintError:ArrayIndexIsNegative`

---

<sup>29</sup>All these utilities, as well as `\xintAssign`, `\xintAssignArray` and the `\xintFor` loops are now available from the `xinttools` package, independently of the big integers facilities of `xint`.

```
\xintError:ArrayIndexBeyondLimit
\xintError:FactorialOfNegativeNumber
\xintError:FactorialOfTooBigNumber
\xintError:DivisionByZero
\xintError:NaN
\xintError:FractionRoundedToZero
\xintError:NotAnInteger
\xintError:ExponentTooBig
\xintError:TooBigDecimalShift
\xintError:TooBigDecimalSplit
\xintError:RootOfNegative
\xintError:NoBezoutForZeros
\xintError:ignored
\xintError:removed
\xintError:inserted
\xintError:use_xintthe!
\xintError:bigtroubleahead
\xintError:unknownfunction
```

## 19 Common input errors when using the package macros

Here is a list of common input errors. Some will cause compilation errors, others are more annoying as they may pass through unsignaled.

- using - to prefix some macro: `-\xintiSqr{35}/271`.<sup>30</sup>
- using one pair of braces too many `\xintIrr{{\xintiPow {3}{13}}/243}` (the computation goes through with no error signaled, but the result is completely wrong).
- using [] and decimal points at the same time `1.5/3.5[2]`, or with a sign in the denominator `3/-5[7]`. The scientific notation has no such restriction, the two inputs `1.5/-3.5e-2` and `-1.5e2/3.5` are equivalent: `\xintRaw{1.5/-3.5e-2} =-15/35[2], \xintRaw{-1.5e2/3.5}=-15/35[2]`.
- specifying numerators and denominators with macros producing fractions when **xintfrac** is loaded: `\edef\x{\xintMul {3}{5}/\xintMul{7}{9}}`. This expands to `15/1[0]/63/1[0]` which is invalid on input. Using this \x in a fraction macro will most certainly cause a compilation error, with its usual arcane and undecipherable accompanying message. The fix here would be to use `\xintiMul`. The simpler alternative with package **xintexpr**: `\xinttheexpr 3*5/(7*9)\relax`.
- generally speaking, using in a context expecting an integer (possibly restricted to the T<sub>E</sub>X bound) a macro or expression which returns a fraction: `\xinttheexpr 4/2\relax` outputs `4/2[0]`, not 2. Use `\xintNum {\xinttheexpr 4/2\relax}` or `\xinttheiexpr 4/2\relax`.

---

<sup>30</sup>to the contrary, this *is* allowed inside an `\xintexpr`-ession.

## 20 Package namespace

Inner macros of **xinttools**, **xint**, **xintfrac**, **xintexpr**, **xintbinhex**, **xintgcd**, **xintseries**, and **xintcfrac** all begin either with `\XINT_` or with `\xint_`.<sup>31</sup> The package public commands all start with `\xint`. Some other control sequences are used only as delimiters, and left undefined, they may have been defined elsewhere, their meaning doesn't matter and is not touched.

**xinttools** defines `\oedef`, `\oodef`, `\fdef`, but only if macros with these names do not already exist (`\XINT_oodef` etc... are defined anyhow for use in `\xintAssign` and `\xintAssignArray`).

## 21 Loading and usage

```
Usage with LaTeX: \usepackage{xinttools}
                  \usepackage{xint}          % (loads xinttools)
                  \usepackage{xintfrac}       % (loads xint)
                  \usepackage{xintexpr}       % (loads xintfrac)

                  \usepackage{xintbinhex}    % (loads xint)
                  \usepackage{xintgcd}        % (loads xint)
                  \usepackage{xintseries}     % (loads xintfrac)
                  \usepackage{xintcfrac}      % (loads xintfrac)

Usage with TeX:   \input xinttools.sty\relax
                  \input xint.sty\relax      % (loads xinttools)
                  \input xintfrac.sty\relax  % (loads xint)
                  \input xintexpr.sty\relax  % (loads xintfrac)

                  \input xintbinhex.sty\relax % (loads xint)
                  \input xintgcd.sty\relax   % (loads xint)
                  \input xintseries.sty\relax % (loads xintfrac)
                  \input xintcfrac.sty\relax  % (loads xintfrac)
```

We have added, directly copied from packages by HEIKO OBERDIEK, a mechanism of reload and  $\varepsilon$ -TeX detection, especially for Plain TeX. As  $\varepsilon$ -TeX is required, the executable `tex` can not be used, `etex` or `pdftex` (version 1.40 or later) or ..., must be invoked. Each package refuses to be loaded twice and automatically loads the other components on which it has dependencies.

Also initially inspired from the HEIKO OBERDIEK packages we have included a complete catcode protection mechanism. The packages may be loaded in any catcode configuration satisfying these requirements: the percent is of category code comment character, the backslash is of category code escape character, digits have category code other and letters have category code letter. Nothing else is assumed, and the previous configuration is restored after the loading of each one of the packages.

---

<sup>31</sup>starting with release 1.06b the style files use for macro names a more modern underscore `_` rather than the `@` sign. A handful of private macros starting with `\XINT` do not have the underscore for technical reasons: `\XINTsetupcatcodes`, `\XINTdigits` and macros with names starting with `XINTinFloat` or `XINTinfloat`.

This is for the loading of the packages.

For the input of numbers as macro arguments the minus sign must have its standard category code (“*other*”). Similarly the slash used for fractions must have its standard category code. And the square brackets, if made use of in the input, also must be of category code *other*. The ‘e’ of the scientific notation must be of category code letter.

All of those requirements are relaxed for tokens parsed inside an `\xintexpr`-ession (but arguments to macros which have been inserted in the expression must obey the rules, as it is the macro and not the parser which will get the tokens). In an `\xintexpr`-ession, the ‘e’ may be uppercased: ‘E’.

- New! → The **xint** packages presuppose that the `\space`, `\empty`, `\m@ne`, `\z@` and `\@ne` control sequences have their meanings as in Plain T<sub>E</sub>X or L<sup>A</sup>T<sub>E</sub>X2e.

## 22 Installation

### A. Installation using `xint.tds.zip`:

```
-----
obtain xint.tds.zip from CTAN:
http://www.ctan.org/tex-archive/install/macros/generic/xint.tds.zip

cd to the download repertory and issue
  unzip xint.tds.zip -d <TEXMF>
for example: (assuming standard access rights, so sudo needed)
  sudo unzip xint.tds.zip -d /usr/local/texlive/texmf-local
  sudo mktexlsr
```

On Mac OS X, installation into user home folder:

```
  unzip xint.tds.zip -d ~/Library/texmf
```

### B. Installation after file extractions:

```
-----
obtain xint.dtx, xint.ins and the README from CTAN:
http://www.ctan.org/tex-archive/macros/generic/xint
```

- “tex xint.ins” generates the style files  
(pre-existing files in the same repertory will be overwritten).
- without xint.ins: “tex or latex or pdflatex or xelatex xint.dtx”  
will also generate the style files (and xint.ins).

`xint.tex` is also extracted, use it for the documentation:

- with `latex+dvipdfmx`: `latex xint.tex` thrice then `dvipdfmx xint.dvi`  
Ignore dvipdfmx warnings. In case the pdf file has problems with  
fonts, use then rather `pdflatex` or `xelatex`.
- with `pdflatex` or `xelatex`: run it directly thrice on `xint.dtx`, or run  
it on `xint.tex` after having edited the suitable toggle therein.

When compiling `xint.tex`, the documentation is by default produced  
with the source code included. See instructions in the file for  
changing this default.

When compiling directly `xint.dtx`, the documentation is produced without the source code (`latex+dvips` or `pdflatex` or `xelatex`).

Finishing the installation: (on first installation the destination repertoires may need to be created)

```

xinttools.sty |
    xint.sty |
    xintfrac.sty |
    xintexpr.sty | --> TDS:tex/generic/xint/
xintbinhex.sty |
    xintgcd.sty |
xintseries.sty |
    xintcfrac.sty |

    xint.dtx   --> TDS:source/generic/xint/
    xint.ins   --> TDS:source/generic/xint/
    xint.tex   --> TDS:source/generic/xint/

    xint.pdf   --> TDS:doc/generic/xint/
    README    --> TDS:doc/generic/xint/

```

Depending on the TDS destination and the TeX installation, it may be necessary to refresh the TeX installation filename database (`mktexlsr`)

## 23 The `\xintexpr` math parser (I)

Here is some random formula, defining a `LATEX` command with three parameters,

`\newcommand\formula[3]`

```
{\xinttheexpr round((#1 & (#2 | #3)) * (355/113/#3 - (#1 - #2/2)^2), 8) \relax}
```

Let `a=#1`, `b=#2`, `c=#3` be the parameters. The first term is the logical operation `a` and (`b` or `c`) where a number or fraction has truth value 1 if it is non-zero, and 0 otherwise. So here it means that `a` must be non-zero as well as `b` or `c`, for this first operand to be 1, else the formula returns 0. This multiplies a second term which is algebraic. Finally the result (where all intermediate computations are done *exactly*) is rounded to a value with 8 digits after the decimal mark, and printed.

`\formula {771.3/9.1}{1.51e2}{37.73} expands to 32.81726043`

- as everything gets expanded, the characters `+, -, *, /, ^, !, &, |, ?, :, <, >, =, (, )` and the comma `(,)`, which are used in the infix syntax, should not be active (for example if they serve as shorthands for some language in the Babel system) at the time of the expressions (if they are in use therein). The command `\xintexprSafeCatcodes` resets these characters to their standard catcodes and `\xintexprRestoreCatcodes` restores the status prevailing at the time of the previous `\xintexprSafeCatcodes`.

- the formula may be input without `\xinttheexpr` through suitable nesting of various package macros. Here one could use:

```

\xintRound {8}{\xintMul {\xintAND {\#1}{\xintOR {\#2}{\#3}}}{\xintSub
{\xintMul {355/113}{\#3}}{\xintPow {\xintSub {\#1}{\xintDiv {\#2}{2}}}{2}}}}
with the inherent difficulty of keeping up with braces and everything...

```

- if such a formula is used thousands of times in a document (for plots?), this could impact some parts of the `\TeX` program memory (for technical reasons explained in [section 29](#)). So, a utility `\xintNewExpr` is provided to do the work of translating an `\xintexpr`-ession with parameters into a chain of macro evaluations.<sup>32</sup>

```
\xintNewExpr\formula[3]
```

```
{ round((#1 & (#2 | #3)) * (355/113*#3 - (#1 - #2/2)^2), 8) }
```

one gets a command `\formula` with three parameters and meaning:

```
macro:#1#2#3->\romannumeral -'0\xintRound {\xintNum {8}}{\xintMul
{\xintAND {#1}{\xintOR {#2}{#3}}}{\xintSub {\xintMul {\xintDiv
{355}{113}}{#3}}{\xintPow {\xintSub {#1}{\xintDiv {#2}{2}}}{2}}}}
```

This does the same thing as the hand-written version from the previous item. The use even thousands of times of such an `\xintNewExpr`-generated `\formula` has no memory impact.

New!

- count registers and `\numexpr`-essions are accepted (`\TeX`'s counters can be inserted using `\value`) without needing `\the` or `\number` as prefix. Also dimen registers and control sequences, skip registers and control sequences (`\TeX`'s lengths), `\dimexpr`-essions, `\glueexpr`-essions are automatically unpacked using `\number`, discarding the stretch and shrink components and giving the dimension value in sp units (1/65536th of a `\TeX` point). Furthermore, tacit multiplication is implied, when immediately prefixed by a (decimal) number.
- like a `\numexpr`, an `\xintexpr` is not directly printable, one uses equivalently `\xintthe\mathop{\xintexpr}` or `\xintthe\mathop{\xintexpr}`. One may for example define:
 

```
\def\x {\xintexpr \a + \b \relax} \def\y {\xintexpr \x * \a \relax}
```

 where `\x` could have been set up equivalently as `\def\x {(\a + \b)}` but the earlier method is better than with parentheses, as it allows `\xintthe\x`.
- sometimes one needs an integer, not a fraction or decimal number. The `round` function rounds to the nearest integer (half-integers are rounded towards  $\pm\infty$ ), and `\xintexpr` `round(...)\relax` has an alternative syntax as `\xintiexpr ... \relax`. There is also `\xinttheiexpr`. The rounding is applied to the final result only.

New!

- `\xintiexpr ... \relax` (`\xinttheiexpr`) is another variant which deals only with (long) integers and skips the overhead of the fraction internal format. The infix operator `/` does euclidean division.
- there is also `\xintboolexpr ... \relax` and `\xinttheboolexpr ... \relax`. Same as regular expression but the final result is converted to 1 if it is not zero. See also `\xintifboolexpr` ([subsection 29.11](#)) and the `discussion` of the `bool` and `togl` functions in [section 23](#). Here is an example:

```
\xintNewBoolExpr \AssertionA[3]{ #1 & (#2|#3) }
\xintNewBoolExpr \AssertionB[3]{ #1 | (#2&#3) }
\xintNewBoolExpr \AssertionC[3]{ xor(#1,#2,#3) }
\xintFor #1 in {0,1} \do {%
  \xintFor #2 in {0,1} \do {%
```

---

<sup>32</sup>As its makes some macro definitions, it is not an expandable command. It does not need protection against active characters as it does it itself.

```
\xintFor #3 in {0,1} \do {%
\centerline{\#1 AND (#2 OR #3) is \AssertionA {\#1}{\#2}{\#3}\hfil
           \#1 OR (#2 AND #3) is \AssertionB {\#1}{\#2}{\#3}\hfil
           \#1 XOR #2 XOR #3 is \AssertionC {\#1}{\#2}{\#3}}}}
```

0 AND (0 OR 0) is 0	0 OR (0 AND 0) is 0	0 XOR 0 XOR 0 is 0
0 AND (0 OR 1) is 0	0 OR (0 AND 1) is 0	0 XOR 0 XOR 1 is 1
0 AND (1 OR 0) is 0	0 OR (1 AND 0) is 0	0 XOR 1 XOR 0 is 1
0 AND (1 OR 1) is 0	0 OR (1 AND 1) is 1	0 XOR 1 XOR 1 is 0
1 AND (0 OR 0) is 0	1 OR (0 AND 0) is 1	1 XOR 0 XOR 0 is 1
1 AND (0 OR 1) is 1	1 OR (0 AND 1) is 1	1 XOR 0 XOR 1 is 0
1 AND (1 OR 0) is 1	1 OR (1 AND 0) is 1	1 XOR 1 XOR 0 is 0
1 AND (1 OR 1) is 1	1 OR (1 AND 1) is 1	1 XOR 1 XOR 1 is 1

- there is also `\xintfloatexpr ... \relax` where the algebra is done in floating point approximation (also for each intermediate result). Use the syntax `\xintDigits:=N;` to set the precision. Default: 16 digits.

```
\xintthefloatexpr 2^100000\relax: 9.990020930143845e30102
```

The square-root operation can be used in `\xintexpr`, it is computed as a float with the precision set by `\xintDigits` or by the optional second argument:

```
\xinttheexpr sqrt(2,60)\relax:
```

```
141421356237309504880168872420969807856967187537694807317668[-59]
```

Notice the  $a/b[n]$  notation (usually  $/b$  even if  $b=1$  gets printed; this is the exception) which is the default format of the macros of the `xintfrac` package (hence of `\xintexpr`). To get a float format from the `\xintexpr` one needs something more:

```
\xintFloat[60]{\xinttheexpr sqrt(2,60)\relax}:
```

```
1.41421356237309504880168872420969807856967187537694807317668e0
```

The precision used by `\xintfloatexpr` must be set by `\xintDigits`, it can not be passed as an option to `\xintfloatexpr`.

```
\xintDigits:=48; \xintthefloatexpr 2^100000\relax:
```

```
9.99002093014384507944032764330033590980429139054e30102
```

FLOATS are quickly indispensable when using the power function (which can only have an integer exponent), as exact results will easily have hundreds of digits.

## 24 The `\xintexpr` math parser (II)

An expression is built with infix operators (including comparison and boolean operators), parentheses, functions, and the two branching operators `?` and `:`. The parser expands everything from the left to the right and everything may thus be revealed step by step by expansion of macros. Spaces anywhere are allowed.

Note that  $2^{-10}$  is perfectly accepted input, no need for parentheses, as well as  $2^{4^8}$  (which is evaluated as  $(2^4)^8$ ). The minus sign as prefix has various precedence levels: `\xintexpr -3-4*-5^-7\relax` evaluates as  $(-3)-(4*(-(5^{(-7)})))$  and  $-3^{4*-5-7}$  as  $(-((3^{-4})*(-5)))-7$ .

The characters used in the syntax should not be active. Use `\xintexprSafeCatcodes`, `\xintexprRestoreCatcodes` if need be (these commands must be exercised out of expansion only context). Apart from that infix operators may be of catcode letter or other, it

does not matter, or even of catcode tabulation, math superscript, or math subscript. This should cause no problem. As an alternative to `\xintexprSafeCatcodes` one may also use `\string` inside the expression.

The `A/B[N]` notation is the output format of most `xintfrac` macros,<sup>33</sup> but for user input in an `\xintexpr..\relax` such a fraction should be written with the scientific notation `AeN/B` (possibly within parentheses) or *braces* must be used: `{A/B[N]}`. The square brackets are *not parseable* if not enclosed in braces together with the fraction.

Braces are also allowed in their usual rôle for arguments to macros (these arguments are thus not seen by the scanner), or to encapsulate *arbitrary* completely expandable material which will not be parsed but completely expanded and *must* return an integer or fraction possibly with decimal mark or in `A/B[N]` notation, but is not allowed to have the `e` or `E`. Braced material is not allowed to expand to some infix operator or parenthesis, it is allowed only in locations where the parser expects to find a number or fraction, possibly with decimal marks, but no `e` nor `E`.

One may use sub-`\xintexpr`-expressions nested within a larger one. It is allowed to alternate `\xintfloatexpr`-essions with `\xintexpr`-essions. Do not use `\xinttheexpr` inside an `\xintexpr`: this gives a number in `A/B[n]` format which requires protection by braces. Do not put within braces numbers in scientific notation.

New!

- See subsection 29.8 for the speed-optimized variant `\xintiiexpr` which deals only with long integers.

Here is, listed from the highest priority to the lowest, the complete list of operators and functions. Functions are at the top level of priority. Next are the postfix operators: `!` for the factorial, `?` and `:` are two-fold way and three-fold way branching constructs. Then the `e` and `E` of the scientific notation, the power, multiplication/division, addition/subtraction, comparison, and logical operators. At the lowest level: commas then parentheses.

The `\relax` at the end of an expression is absolutely *mandatory*.

- Functions are at the same top level of priority.

**functions with one (numeric) argument** (numeric: any expression leading to an integer, decimal number, fraction, or floating number in scientific notation) `floor`, `ceil`, `frac`, `reduce`, `sqr`, `abs`, `sgn`, `?`, `!`, `not`. The `?(x)` function returns the truth value, 1 if  $x > 0$ , 0 if  $x = 0$ . The `!(x)` is the logical not. The `reduce` function puts the fraction in irreducible form. The `frac` function is fractional part (same sign as the number, complements truncation towards zero). Like the other functions `!` and `?` *must* use parentheses.

New

- fraction in irreducible form. The `frac` function is fractional part (same sign as the number, complements truncation towards zero). Like the other functions `!` and `?` *must* use parentheses.

**functions with one (alphabetical) argument** `bool`, `togl`. `bool(name)` returns 1 if the `\TeX` conditional `\ifname` would act as `\iftrue` and 0 otherwise. This works with conditionals defined by `\newif` (in `\TeX` or `\LaTeX`) or with primitive conditionals such as `\ifmmode`. For example:

```
\xintifboolexpr{25*4-if(bool(\mmode),100,75)}{YES}{NO}
```

will return `NO` if executed in math mode (the computation is then  $100 - 100 = 0$ ) and `YES` if not (the `if` conditional is described below; the `\xintifboolexpr` test automatically encapsulates its first argument in an `\xintexpr` and follows the first branch if the result is non-zero (see subsection 29.11)).

<sup>33</sup>this format is convenient for nesting macros; when displaying the final result of a computation one has `\xintFrac` in math mode, or `\xintIrr` and also `\xintPRaw` for inline text mode.

The alternative syntax `25*4-\ifmmode100\else75\fi` could have been used here, the usefulness of `bool(name)` lies in the availability in the `\xintexpr` syntax of the logic operators of conjunction `&`, inclusive disjunction `|`, negation `!` (or `not`), of the multi-operands functions `all`, `any`, `xor`, of the two branching operators `if` and `ifsgn` (see also `? and :`), which allow arbitrarily complicated combinations of various `bool(name)`.

Similarly `togl(name)` returns 1 if the L<sup>A</sup>T<sub>E</sub>X package `etoolbox`<sup>34</sup> has been used to define a toggle named `name`, and this toggle is currently set to `true`. Using `togl` in an `\xintexpr... \relax` without having loaded `etoolbox` will result in an error from `\iftoggle` being a non-defined macro. If `etoolbox` is loaded but `togl` is used on a name not recognized by `etoolbox` the error message will be of the type “ERROR: Missing `\endcsname` inserted.”, with further information saying that `\protect` should have not been encountered (this `\protect` comes from the expansion of the non-expandable `etoolbox` error message).

When `bool` or `togl` is encountered by the `\xintexpr` parser, the argument enclosed in a parenthesis pair is expanded as usual from left to right, token by token, until the closing parenthesis is found, but everything is taken literally, no computations are performed. For example `togl(2+3)` will test the value of a toggle declared to `etoolbox` with name `2+3`, and not 5. Spaces are gobbled in this process. It is impossible to use `togl` on such names containing spaces, but `\iftoggle{name with spaces}{1}{0}` will work, naturally, as its expansion will pre-empt the `\xintexpr` scanner.

There isn’t in `\xintexpr... a test` function available analogous to the `test{\ifsometest}` construct from the `etoolbox` package; but any *expandable* `\ifsometest` can be inserted directly in an `\xintexpr`-ession as `\ifsometest10` (or `\ifsometest{1}{0}`), for example `if(\ifsometest{1}{0}, YES, NO)` (see the `if` operator below) works.

A straight `\ifsometest{YES}{NO}` would do the same more efficiently, the point of `\ifsometest10` is to allow arbitrary boolean combinations using the (described later) `&` and `|` logic operators: `\ifsometest10 & \ifsomeothertest10 | \ifsomethirdtest10`, etc... `YES` or `NO` above stand for material compatible with the `\xintexpr` parser syntax.

See also `\xintifboolexpr`, in this context.

**functions with one mandatory and a second optional argument** `round`, `trunc`, `float`, `sqrt`. For example `round(2^9/3^5,12)=2.106995884774`. The `sqrt` is available also in `\xintexpr`, not only in `\xintfloatexpr`. The second optional argument is then the required float precision.

**functions with two arguments** `quo`, `rem`. These functions are integer only, they give the quotient and remainder in Euclidean division (more generally one can use the `floor` function; related: the `frac` function).

**the if conditional (twofold way)** `if(cond,yes,no)` checks if `cond` is true or false and takes the corresponding branch. Any non zero number or fraction is logical true. The zero value is logical false. Both “branches” are evaluated (they are not really branches but just numbers). See also the `?` operator.

**the ifsgn conditional (threefold way)** `ifsgn(cond,<0,=0,>0)` checks the sign of `cond` and proceeds correspondingly. All three are evaluated. See also the `:` operator.

<sup>34</sup><http://www.ctan.org/pkg/etoolbox>

**functions with an arbitrary number of arguments** `all`, `any`, `xor`, `add (=sum)`, `mul (=prd)`, `max`, `min`, `gcd`, `lcm`: the last two are integer-only and require the `xintgcd` package. Currently, `and` and `or` are left undefined, and the package uses the vocabulary `all` and `any`. They must have at least one argument.

- The three postfix operators:

`!` computes the factorial of an integer. `sqrt(36)!` evaluates to  $6! (=720)$  and not to the square root of  $36! (\approx 6.099,125,566,750,542 \times 10^{20})$ . This is the exact factorial even when used inside `\xintfloatexpr`.

`?` is used as `(cond)?{yes}{no}`. It evaluates the (numerical) condition (any non-zero value counts as `true`, zero counts as `false`). It then acts as a macro with two mandatory arguments within braces (hence this escapes from the parser scope, the braces can not be hidden in a macro), chooses the correct branch *without evaluating the wrong one*. Once the braces are removed, the parser scans and expands the uncovered material so for example

```
\xinttheiexpr (3>2)?{5+6}{7-1}2^3\relax
```

is legal and computes  $5+62^3=238333$ . Note though that it would be better practice to include here the  $2^3$  inside the branches. The contents of the branches may be arbitrary as long as once glued to what is next the syntax is respected: `\xintexpr (3>2)?{5+(6}{7-(1)2^3}\relax` also works. Differs thus from the `if` conditional in two ways: the false branch is not at all computed, and the number scanner is still active on exit, more digits may follow.

`:` is used as `(cond):{<0}{=0}{>0}`. `cond` is anything, its sign is evaluated (it is not necessary to use `sgn(cond):{<}{=}{>}`) and depending on the sign the correct branch is un-braced, the two others are swallowed. The un-braced branch will then be parsed as usual. Differs from the `ifsgn` conditional as the two false branches are not evaluated and furthermore the number scanner is still active on exit.

```
\def\x{0.33}\def\y{1/3}
\xinttheexpr (\x-\y):\{sqrt\}{0}{1/}(\y-\x)\relax=5773502691896258[-17]
```

- The `e` and `E` of the scientific notation. They are treated as infix operators of highest priority. The decimal mark is scanned in a special direct way: in `1.12e3` first `1.12` is formed then only `e` is found. `1e3-1` is `999`.

- The power operator `^`. It is left associative: `\xinttheiexpr 2^2^3\relax` evaluates to `64`, not `256`.
- Multiplication and division `*`, `/`. The division is left associative, too: `\xinttheiexpr 100/50/2\relax` evaluates to `1`, not `4`.
- Addition and subtraction `+`, `-`. Again, `-` is left associative: `\xinttheiexpr 100-50-2\relax` evaluates to `48`, not `52`.
- Comparison operators `<`, `>`, `=`.
- Conjunction (logical and): `&`.
- Inclusive disjunction (logical or): `|`.

- The comma `,`. One can thus do `\xinttheiexpr 2^3,3^4,5^6\relax` and obtain as output 8,81,15625.
- The parentheses.

See [subsection 29.2](#) for count and dimen registers and variables.

## 25 Change log for earlier releases

Release 1.09h ([2013/11/28]):

- parts of the documentation have been re-written or re-organized, particularly the discussion of expansion issues and of input and output formats.
- the expansion types of macro arguments are documented in the margin of the macro descriptions, with conventions mainly taken over from those in the L<sup>A</sup>T<sub>E</sub>X3 documentation.
- a dependency of `xinttools` on `xint` (inside `\xintSeq`) has been removed.
- `\xintTypesetEuclideanAlgorithm` and `\xintTypesetBezoutAlgorithm` have been slightly modified (regarding indentation).
- macros `\xintiSum` and `\xintiPrd` are renamed to `\xintiiSum` and `\xintiiPrd`.
- a count register used in 1.09g in the `\xintFor` loops for parsing purposes has been removed and replaced by use of a `\numexpr`.
- the few uses of `\loop` have been replaced by `\xintloop/\xintiloop`.
- all macros of `xinttools` for which it makes sense are now declared `\long`.

Release 1.09g ([2013/11/22]):

- package `xinttools` is detached from `xint`, to make tools such as `\xintFor`, `\xintApplyUnbraced`, and `\xintiloop` available without the `xint` overhead.
- new expandable nestable loops `\xintloop` and `\xintiloop`.
- bugfix: `\xintFor` and `\xintFor*` do not modify anymore the value of `\count 255`.

Release 1.09f ([2013/11/04]):

- new `\xintZapFirstSpaces`, `\xintZapLastSpaces`, `\xintZapSpaces`, `\xintZapSpacesB`, for expandably stripping away leading and/or ending spaces.
- `\xintCSVtoList` by default uses `\xintZapSpacesB` to strip away spaces around commas (or at the start and end of the comma separated list).
- also the `\xintFor` loop will strip out all spaces around commas and at the start and the end of its list argument; and similarly for `\xintForpair`, `\xintForthree`, `\xintForfour`.
- `\xintFor` et al. accept all macro parameters from #1 to #9.
- for reasons of inner coherence some macros previously with one extra ‘i’ in their names (e.g. `\xintiMON`) now have a doubled ‘ii’ (`\xintiiMON`) to indicate that they skip the overhead of parsing their inputs via `\xintNum`. Macros with a *single* ‘i’ such as `\xintiAdd` are those which maintain the non-`xintfrac` output format for big integers, but do parse their inputs via `\xintNum` (since release 1.09a). They too may have doubled-i variants for matters of programming optimization when working only with (big) integers and not fractions or decimal numbers, interested advanced users should check the code source.

Release 1.09e ([2013/10/29]):

- new `\xintintegers`, `\xintdimensions`, `\xintrationals` for infinite `\xintFor` loops, interrupted with `\xintBreakFor` and `\xintBreakForAndDo`.
- new `\xintifForFirst`, `\xintifForLast` for the `\xintFor` and `\xintFor*` loops,
- the `\xintFor` and `\xintFor*` loops are now `\long`, the replacement text and the items may contain explicit `\par`s.

## 25 Change log for earlier releases

- bug fix, the `\xintFor` loop (not `\xintFor*`) did not correctly detect an empty list.
- new conditionals `\xintifCmp`, `\xintifInt`, `\xintifOdd`.
- bug fix, `\xintiSqrt {0}` crashed. :-((
- the documentation has been enriched with various additional examples, such as the [the quick sort algorithm illustrated](#) or the computation of prime numbers ([subsection 26.11](#), [subsection 26.14](#), [subsection 26.21](#)).
- the documentation explains with more details various expansion related issues, particularly in relation to conditionals.

Release 1.09d ([2013/10/22]):

- `\xintFor*` is modified to gracefully handle a space token (or more than one) located at the very end of its list argument (as in for example `\xintFor* #1 in {{a}{b}{c}<space>} \do {stuff}`; spaces at other locations were already harmless). Furthermore this new version *f-expands* the un-braced list items. After `\def\x{{1}{2}}` and `\def\y{{a}\x {b}{c}\x }`, `\y` will appear to `\xintFor*` exactly as if it had been defined as `\def\y{{a}{1}{2}{b}{c}{1}{2}}`.
- same bug fix in `\xintApplyInline`.

Release 1.09c ([2013/10/09]):

- added `bool` and `togl` to the `\xintexpr` syntax; also added `\xintboolexpr` and `\xintifboolexpr`.
- added `\xintNewNumExpr` (now `\xintNewIExpr` and `\xintNewBoolExpr`,
- `\xintFor` is a new type of loop, whose replacement text inserts the comma separated values or list items via macro parameters, rather than encapsulated in macros; the loops are nestable up to four levels, and their replacement texts are allowed to close groups as happens with the tabulation in alignments,
- `\xintForpair`, `\xintForthree`, `\xintForfour` are experimental variants of `\xintFor`,
- `\xintApplyInline` has been enhanced in order to be usable for generating rows (partially or completely) in an alignment,
- new command `\xintSeq` to generate (expandably) arithmetic sequences of (short) integers,
- the factorial `!` and branching `?, :` operators (in `\xintexpr... \relax`) have now less precedence than a function name located just before: `func(x) !` is the factorial of `func(x)`, not `func(x!)`,
- again various improvements and changes in the documentation.

Release 1.09b ([2013/10/03]):

- various improvements in the documentation,
- more economical catcode management and re-loading handling,
- removal of all those `[0]`'s previously forcefully added at the end of fractions by various macros of `xintcfrac`,
- `\xintNthElt` with a negative index returns from the tail of the list,
- new macro `\xintPRaw` to have something like what `\xintFrac` does in math mode; i.e. a `\xintRaw` which does not print the denominator if it is one.

Release 1.09a ([2013/09/24]):

- `\xintexpr..\relax` and `\xintfloatexpr..\relax` admit functions in their syntax, with comma separated values as arguments, among them `reduce`, `sqr`, `sqrt`, `abs`, `sgn`, `floor`, `ceil`, `quo`, `rem`, `round`, `trunc`, `float`, `gcd`, `lcm`, `max`, `min`, `sum`, `prd`, `add`, `mul`, `not`, `all`, `any`, `xor`.
  - comparison (`<`, `>`, `=`) and logical (`|`, `&`) operators.
  - the command `\xintthe` which converts `\xintexpressions` into printable format (like `\the` with `\numexpr`) is more efficient, for example one can do `\xintthe\x` if `\x` was defined to be an `\xintexpr..\relax`:
- ```
\def\x{\xintexpr 3^57\relax}\def\y{\xintexpr \x^{(-2)}\relax}
\def\z{\xintexpr \y-3^(-14)\relax} \xintthe\z=0/1[0]
```
- `\xintnumexpr .. \relax` (now renamed `\xintiexpr`) is `\xintexpr round( .. ) \relax`.
  - `\xintNewExpr` now works with the standard macro parameter character `#`.

- both regular `\xintexpr`-essions and commands defined by `\xintNewExpr` will work with comma separated lists of expressions,
- new commands `\xintFloor`, `\xintCeil`, `\xintMaxof`, `\xintMinof` (package **xintfrac**), `\xintGCDof`, `\xintLCM`, `\xintLCMof` (package **xintgcd**), `\xintifLt`, `\xintifGt`, `\xintifSgn`, `\xintANDof`, ...
- The arithmetic macros from package **xint** now filter their operands via `\xintNum` which means that they may use directly count registers and `\numexpr`-essions without having to prefix them by `\the`. This is thus similar to the situation holding previously but with **xintfrac** loaded.
- a bug introduced in 1.08b made `\xintCmp` crash when one of its arguments was zero. :-(

Release 1.08b ([2013/06/14]):

- Correction of a problem with spaces inside `\xintexpr`-essions.
- Additional improvements to the handling of floating point numbers.
- The macros of **xintfrac** allow to use count registers in their arguments in ways which were not previously documented. See [Use of count registers](#).

Release 1.08a ([2013/06/11]):

- Improved efficiency of the basic conversion from exact fractions to floating point numbers, with ensuing speed gains especially for the power function macros `\xintFloatPow` and `\xintFloatPower`,
- Better management by the **xintfrac** macros `\xintCmp`, `\xintMax`, `\xintMin` and `\xintGeq` of inputs having big powers of ten in them.
- Macros for floating point numbers added to the **xintseries** package.

Release 1.08 ([2013/06/07]):

- Extraction of square roots, for floating point numbers (`\xintFloatSqrt`), and also in a version adapted to integers (`\xintiSqrt`).
- New package **xintbinhex** providing [conversion routines](#) to and from binary and hexadecimal bases.

Release 1.07 ([2013/05/25]):

- The **xintfrac** macros accept numbers written in scientific notation, the `\xintFloat` command serves to output its argument with a given number D of significant figures. The value of D is either given as optional argument to `\xintFloat` or set with `\xintDigits := D;`. The default value is 16.
- The **xintexpr** package is a new core constituent (which loads automatically **xintfrac** and **xint**) and implements the expandable expanding parsers  
`\xintexpr . . . \relax`, and its variant `\xintfloatexpr . . . \relax`  
allowing on input formulas using the standard form with infix operators +, -, \*, /, and ^, and arbitrary levels of parenthesizing. Within a float expression the operations are executed according to the current value of `\xintDigits`. Within an `\xintexpr`-ession the binary operators are computed exactly.
- The floating point precision D is set (this is a local assignment to a `\mathchar` variable) with `\xintDigits := D;` and queried with `\xinttheDigits`. It may be set to anything up to 32767.<sup>35</sup> The macro incarnations of the binary operations admit an optional argument which will replace pointwise D; this argument may exceed the 32767 bound.
- To write the `\xintexpr` parser I benefited from the commented source of the L<sup>A</sup>T<sub>E</sub>X3 parser; the `\xintexpr` parser has its own features and peculiarities. See [its documentation](#).

Initial release 1.0 was on 2013/03/28.

## 26 Commands of the **xinttools** package

These utilities used to be provided within the **xint** package; since 1.09g they have been moved to an independently usable package **xinttools**, which has none of the **xint** facilities regarding big numbers. Whenever relevant release 1.09h has made the macros `\long` so they accept `\par` tokens on input.

---

<sup>35</sup>but values higher than 100 or 200 will presumably give too slow evaluations.

First the completely expandable utilities up to `\xintiloop`, then the non expandable utilities.

This section contains various concrete examples and ends with a completely expandable implementation of the Quick Sort algorithm together with a graphical illustration of its action.

| .14 | Another completely expandable prime test                                                                                                                   | 48 |  |  |
| .15 | A table of factorizations                                                                                                                                  | 49 |  |  |
| .16 | <code>\xintApplyInline</code>                                                                                                                              | 50 |  |  |
| .17 | <code>\xintFor</code> , <code>\xintFor*</code>                                                                                                             | 53 |  |  |
| .18 | <code>\xintifForFirst</code> , <code>\xintifForLast</code>                                                                                                 | 56 |  |  |
| .19 | <code>\xintBreakFor</code> , <code>\xintBreakForAndDo</code>                                                                                               | 56 |  |  |
| .20 | <code>\xintintegers</code> , <code>\xintdimensions</code> , <code>\xintrationals</code>                                                                    | 56 |  |  |
| .21 | Another table of primes                                                                                                                                    | 58 |  |  |
| .22 | <code>\xintForpair</code> , <code>\xintForthree</code> ,<br><code>\xintForfour</code>                                                                      | 59 |  |  |
| .23 | <code>\xintAssign</code>                                                                                                                                   | 60 |  |  |
| .24 | <code>\xintAssignArray</code>                                                                                                                              | 60 |  |  |
| .25 | <code>\xintRelaxArray</code>                                                                                                                               | 61 |  |  |
| .26 | <code>\odef</code> , <code>\oodef</code> , <code>\fdef</code>                                                                                              | 61 |  |  |
| .27 | The Quick Sort algorithm illustrated                                                                                                                       | 62 |  |  |

### 26.1 `\xintReverseOrder`

- n* ★ `\xintReverseOrder{<list>}` does not do any expansion of its argument and just reverses the order of the tokens in the `<list>`. Braces are removed once and the enclosed material, now unbraced, does not get reverted. Unprotected spaces (of any character code) are gobbled.

```
\xintReverseOrder{\xintDigitsOf\xintiPow {2}{100}\to\Stuff}
gives: \Stuff\to1002\xintiPow\xintDigitsOf
```

### 26.2 `\xintRevWithBraces`

- f* ★ `\xintRevWithBraces{<list>}` first does the *f*-expansion of its argument then it reverses the order of the tokens, or braced material, it encounters, adding a pair of braces to each (thus, maintaining brace pairs already existing). Spaces (in-between external brace pairs) are gobbled. This macro is mainly thought out for use on a `<list>` of such braced material; with such a list as argument the *f*-expansion will only hit against the first opening brace, hence do nothing, and the braced stuff may thus be macros one does not want to expand.

```
\edef\x{\xintRevWithBraces{12345}}
\meaning\x:macro:->{5}{4}{3}{2}{1}
    \edef\y{\xintRevWithBraces\x}
\meaning\y:macro:->{1}{2}{3}{4}{5}
```

The examples above could be defined with `\edef`'s because the braced material did not contain macros. Alternatively:

```
\expandafter\def\expandafter\w\expandafter
{\romannumerical0\xintrevwithbraces{{\A}{\B}{\C}{\D}{\E}}}
\meaning\w:macro:->{\E }{\D }{\C }{\B }{\A }
```

- n ★ The macro `\xintReverseWithBracesNoExpand` does the same job without the initial expansion of its argument.

### 26.3 `\xintLength`

- n ★ `\xintLength{⟨list⟩}` does not do *any* expansion of its argument and just counts how many tokens there are (possibly none). So to use it to count things in the replacement text of a macro one should do `\expandafter\xintLength\expandafter{⟨x⟩}`. One may also use it inside macros as `\xintLength{#1}`. Things enclosed in braces count as one. Blanks between tokens are not counted. See `\xintNthElt{0}` for a variant which first *f*-expands its argument.

```
\xintLength {\xintiPow {2}{100}}=3
# \xintLen {\xintiPow {2}{100}}=31
```

### 26.4 `\xintZapFirstSpaces`, `\xintZapLastSpaces`, `\xintZapSpaces`, `\xintZapSpacesB`

- n ★ `\xintZapFirstSpaces{⟨stuff⟩}` does not do *any* expansion of its argument, nor brace removal of any sort, nor does it alter `⟨stuff⟩` in anyway apart from stripping away all *leading* spaces.

This macro will be mostly of interest to programmers who will know what I will now be talking about. *The essential points, naturally, are the complete expandability and the fact that no brace removal nor any other alteration is done to the input.*

`TEX`'s input scanner already converts consecutive blanks into single space tokens, but `\xintZapFirstSpaces` handles successfully also inputs with consecutive multiple space tokens. However, it is assumed that `⟨stuff⟩` does not contain (except inside braced submaterial) space tokens of character code distinct from 32.

It expands in two steps, and if the goal is to apply it to the expansion text of `\x` to define `\y`, then one should do: `\expandafter\def\expandafter\y\expandafter {\romannumerical0\expandafter\xintzapfirstspaces\expandafter{⟨x⟩}}`.

Other use case: inside a macro as `\edef\x{\xintZapFirstSpaces {#1}}` assuming naturally that #1 is compatible with such an `\edef` once the leading spaces have been stripped.

```
\xintZapFirstSpaces { \a { \X } { \b \Y } }->\a { \X } { \b \Y } +++
```

- n ★ `\xintZapLastSpaces{⟨stuff⟩}` does not do *any* expansion of its argument, nor brace removal of any sort, nor does it alter `⟨stuff⟩` in anyway apart from stripping away all *ending* spaces. The same remarks as for `\xintZapFirstSpaces` apply.

```
\xintZapLastSpaces { \a { \X } { \b \Y } }-> \a { \X } { \b \Y }+++
```

- n ★* `\xintZapSpaces{⟨stuff⟩}` does not do *any* expansion of its argument, nor brace removal of any sort, nor does it alter `⟨stuff⟩` in anyway apart from stripping away all *leading* and all *ending* spaces. The same remarks as for `\xintZapFirstSpaces` apply.

```
\xintZapSpaces { \a { \X } { \b \Y } }->\a { \X } { \b \Y }+++
```

- n ★* `\xintZapSpacesB{⟨stuff⟩}` does not do *any* expansion of its argument, nor does it alter `⟨stuff⟩` in anyway apart from stripping away all leading and all ending spaces and possibly removing one level of braces if `⟨stuff⟩` had the shape `<spaces>{braced}<spaces>`. The same remarks as for `\xintZapFirstSpaces` apply.

```
\xintZapSpacesB { \a { \X } { \b \Y } }->\a { \X } { \b \Y }+++
```

```
\xintZapSpacesB { { \a { \X } { \b \Y } } }->\a { \X } { \b \Y } +++
```

The spaces here at the start and end of the output come from the braced material, and are not removed (one would need a second application for that; recall though that the **xint** zapping macros do not expand their argument).

## 26.5 `\xintCSVtoList`

- f ★* `\xintCSVtoList{a,b,c...,z}` returns `{a}{b}{c}...{z}`. A *list* is by convention in this manual simply a succession of tokens, where each braced thing will count as one item (“items” are defined according to the rules of **T<sub>E</sub>X** for fetching undelimited parameters of a macro, which are exactly the same rules as for **L<sup>A</sup>T<sub>E</sub>X** and command arguments [they are the same things]). The word ‘list’ in ‘comma separated list of items’ has its usual linguistic meaning, and then an “item” is what is delimited by commas.

So `\xintCSVtoList` takes on input a ‘comma separated list of items’ and converts it into a ‘**T<sub>E</sub>X** list of braced items’. The argument to `\xintCSVtoList` may be a macro: it will first be *f-expanded*. Hence the item before the first comma, if it is itself a macro, will be expanded which may or may not be a good thing. A space inserted at the start of the first

- n ★* item serves to stop that expansion (and disappears). The macro `\xintCSVtoListNoExpand` does the same job without the initial expansion of the list argument.

Apart from that no expansion of the items is done and the list items may thus be completely arbitrary (and even contain perilous stuff such as unmatched `\if` and `\fi` tokens).

Contiguous spaces and tab characters, are collapsed by **T<sub>E</sub>X** into single spaces. All such spaces around commas<sup>36</sup> are removed, as well as the spaces at the start and the spaces at the end of the list.<sup>37</sup> The items may contain explicit `\par`s or empty lines (converted by the **T<sub>E</sub>X** input parsing into `\par` tokens).

```
\xintCSVtoList { 1 , 2 , 3 , 4 , 5 } , a , {b,T} U , { c , d } , { {x , y} } }  
->{1}{2 , 3 , 4 , 5}{a}{ {b,T} U}{ c , d }{ {x , y} }
```

One sees on this example how braces protect commas from sub-lists to be perceived as delimiters of the top list. Braces around an entire item are removed, even when surrounded by spaces before and/or after. Braces for sub-parts of an item are not removed.

---

<sup>36</sup>and multiple space tokens are not a problem; but those at the top level (not hidden inside braces) *must* be of character code 32.

<sup>37</sup>let us recall that this is all done completely expandably... There is absolutely no alteration of any sort of the item apart from the stripping of initial and final space tokens (of character code 32) and brace removal if and only if the item apart from intial and final spaces (or more generally multiple char 32 space tokens) is braced.

We observe also that there is a slight difference regarding the brace stripping of an item: if the braces were not surrounded by spaces, also the initial and final (but no other) spaces of the *enclosed* material are removed. This is the only situation where spaces protected by braces are nevertheless removed.

From the rules above: for an empty argument (only spaces, no braces, no comma) the output is {} (a list with one empty item), for “<opt. spaces>{}<opt. spaces>” the output is {} (again a list with one empty item, the braces were removed), for “{ }” the output is {} (again a list with one empty item, the braces were removed and then the inner space was removed), for “ { }” the output is {} (again a list with one empty item, the initial space served only to stop the expansion, so this was like “{ }” as input, the braces were removed and the inner space was stripped), for “ { } ” the output is {} (this time the ending space of the first item meant that after brace removal the inner spaces were kept; recall though that TeX collapses on input consecutive blanks into one space token), for “,” the output consists of two consecutive empty items {}{}. Recall that on output everything is braced, a {} is an “empty” item. Most of the above is mainly irrelevant for every day use, apart perhaps from the fact to be noted that an empty input does not give an empty output but a one-empty-item list (it is as if an ending comma was always added at the end of the input).

```
\def\y{\a,\b,\c,\d,\e} \xintCSVtoList\y->{\a}{\b}{\c}{\d}{\e}
\def\t{{\if},\ifnum,\ifx,\ifdim,\ifcat,\ifmmode}
\xintCSVtoList\t->{\if}{\ifnum}{\ifx}{\ifdim}{\ifcat}{\ifmmode}
```

The results above were automatically displayed using TeX’s primitive `\meaning`, which adds a space after each control sequence name. These spaces are not in the actual braced items of the produced lists. The first items `\a` and `\if` were either preceded by a space or braced to prevent expansion. The macro `\xintCSVtoListNoExpand` would have done the same job without the initial expansion of the list argument, hence no need for such protection but if `\y` is defined as `\def\y{\a,\b,\c,\d,\e}` we then must do:

```
\expandafter\xintCSVtoListNoExpand\expandafter {\y}
```

Else, we may have direct use:

```
\xintCSVtoListNoExpand {\if,\ifnum,\ifx,\ifdim,\ifcat,\ifmmode}
->{\if}{\ifnum}{\ifx}{\ifdim}{\ifcat}{\ifmmode}
```

Again these spaces are an artefact from the use in the source of the document of `\meaning` (or rather here, `\detokenize`) to display the result of using `\xintCSVtoListNoExpand` (which is done for real in this document source).

For the similar conversion from comma separated list to braced items list, but without removal of spaces around the commas, there is `\xintCSVtoListNonStripped` and `\xintCSVtoListNonStrippedNoExpand`.

## 26.6 `\xintNthElt`

<sup>num</sup><sub>x</sub> <sup>f★</sup> `\xintNthElt{x}{list}` gets (expandably) the *x*th braced item of the *list*. An unbraced item token will be returned as is. The list itself may be a macro which is first *f*-expanded.

```
\xintNthElt {3}{{agh}\u{zzz}\v{Z}} is zzz
\xintNthElt {3}{{agh}\u{{zzz}}\v{Z}} is {zzz}
\xintNthElt {2}{{agh}\u{{zzz}}}\v{Z} is \u
\xintNthElt {37}{\xintFac {100}}=9 is the thirty-seventh digit of 100!.
\xintNthElt {10}{\xintFtoCv {566827/208524}}=1457/536
```

is the tenth convergent of 566827/208524 (uses **xintcfrac** package).

```
\xintNthElt {7}{\xintCSVtoList {1,2,3,4,5,6,7,8,9}}=7
\xintNthElt {0}{\xintCSVtoList {1,2,3,4,5,6,7,8,9}}=9
\xintNthElt {-3}{\xintCSVtoList {1,2,3,4,5,6,7,8,9}}=7
```

If  $x=0$ , the macro returns the *length* of the expanded list: this is not equivalent to **\xintLength** which does no pre-expansion. And it is different from **\xintLen** which is to be used only on integers or fractions.

If  $x < 0$ , the macro returns the  $x$ th element from the end of the list.

```
\xintNthElt {-5}{{{\{agh\}}}\u{zzz}\v{Z}} is {agh}
```

**num** ***x n*** ★ The macro **\xintNthEltNoExpand** does the same job but without first expanding the list argument: **\xintNthEltNoExpand {-4}{\u\v\w T\x\y\z}** is **T**.

In cases where  $x$  is larger (in absolute value) than the length of the list then **\xintNthElt** returns nothing.

## 26.7 **\xintListWithSep**

**nf** ★ **\xintListWithSep{sep}{<list>}** inserts the given separator **sep** in-between all items of the given list of braced items: this separator may be a macro (or multiple tokens) but will not be expanded. The second argument also may be itself a macro: it is *f*-expanded. Applying **\xintListWithSep** removes the braces from the list items (for example **\{1\}\{2\}\{3\}** turns into **1,2,3** via **\xintListWithSep{,}{\{1\}\{2\}\{3\}}**). An empty input gives an empty output, a singleton gives a singleton, the separator is used starting with at least two elements. Using an empty separator has the net effect of unbracing the braced items constituting the **<list>** (in such cases the new list may thus be longer than the original).

```
\xintListWithSep{ : }{\xintFac {20}}=2:4:3:2:9:0:2:0:0:8:1:7:6:6:4:0:0:0:0
```

**nn** ★ The macro **\xintListWithSepNoExpand** does the same job without the initial expansion.

## 26.8 **\xintApply**

**ff** ★ **\xintApply{\macro}{<list>}** expandably applies the one parameter command **\macro** to each item in the **<list>** given as second argument and returns a new list with these outputs: each item is given one after the other as parameter to **\macro** which is expanded at that time (as usual, *i.e.* fully for what comes first), the results are braced and output together as a succession of braced items (if **\macro** is defined to start with a space, the space will be gobbled and the **\macro** will not be expanded; it is allowed to have its own arguments, the list items serve as last arguments to **\macro**). Hence **\xintApply{\macro}{\{1\}\{2\}\{3\}}** returns **\{macro\{1\}\}\{macro\{2\}\}\{macro\{3\}\}** where all instances of **\macro** have been already *f*-expanded.

Being expandable, **\xintApply** is useful for example inside alignments where implicit groups make standard loops constructs usually fail. In such situation it is often not wished that the new list elements be braced, see **\xintApplyUnbraced**. The **\macro** does not have to be expandable: **\xintApply** will try to expand it, the expansion may remain partial.

The **<list>** may itself be some macro expanding (in the previously described way) to the list of tokens to which the command **\macro** will be applied. For example, if the **<list>** expands to some positive number, then each digit will be replaced by the result of applying **\macro** on it.

```
\def\macro #1{\the\numexpr 9-#1\relax}
\xintApply\macro{\xintFac {20}}=7567097991823359999
```

- fn* ★ The macro `\xintApplyNoExpand` does the same job without the first initial expansion which gave the *list* of braced tokens to which `\macro` is applied.

## 26.9 `\xintApplyUnbraced`

- ff* ★ `\xintApplyUnbraced{\macro}{<list>}` is like `\xintApply`. The difference is that after having expanded its list argument, and applied `\macro` in turn to each item from the list, it reassembles the outputs without enclosing them in braces. The net effect is the same as doing

```
\xintListWithSep {}{\xintApply {\macro}{<list>}}
```

This is useful for preparing a macro which will itself define some other macros or make assignments, as the scope will not be limited by brace pairs.

```
\def\macro #1{\expandafter\def\csname myself#1\endcsname {#1}}
\xintApplyUnbraced\macro{{\elte}{\eltb}{\eltc}}
\meaning\myselfelte: macro:->\elte
\meaning\myselfeltb: macro:->\eltb
\meaning\myselfeltc: macro:->\eltc
```

- fn* ★ The macro `\xintApplyUnbracedNoExpand` does the same job without the first initial expansion which gave the *list* of braced tokens to which `\macro` is applied.

## 26.10 `\xintSeq`

- [<sup>num</sup>]<sub>x</sub> [<sup>num</sup>]<sub>x</sub> [<sup>num</sup>]<sub>x</sub> ★ `\xintSeq[d]{x}{y}` generates expandably `{x}{x+d}...` up to and possibly including `{y}` if  $d > 0$  or down to and including `{y}` if  $d < 0$ . Naturally `{y}` is omitted if  $y - x$  is not a multiple of  $d$ . If  $d = 0$  the macro returns `{x}`. If  $y - x$  and  $d$  have opposite signs, the macro returns nothing. If the optional argument  $d$  is omitted it is taken to be the sign of  $y - x$ .

The current implementation is only for (short) integers; possibly, a future variant could allow big integers and fractions, although one already has access to similar functionality using `\xintApply` to get any arithmetic sequence of long integers. Currently thus, `x` and `y` are expanded inside a `\numexpr` so they may be count registers or a L<sup>A</sup>T<sub>E</sub>X `\value{countername}`, or arithmetic with such things.

```
\xintListWithSep{,\hspace{2pt} plus 1pt minus 1pt }{\xintSeq {12}{-25}}
12, 11, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1, 0, -1, -2, -3, -4, -5, -6, -7, -8, -9, -10,
-11, -12, -13, -14, -15, -16, -17, -18, -19, -20, -21, -22, -23, -24, -25
\xintiiSum{\xintSeq [3]{1}{1000}}=167167
```

**Important:** for reasons of efficiency, this macro, when not given the optional argument  $d$ , works backwards, leaving in the token stream the already constructed integers, from the tail down (or up). But this will provoke a failure of the `tex` run if the number of such items exceeds the input stack limit; on my installation this limit is at 5000.

However, when given the optional argument  $d$  (which may be  $+1$  or  $-1$ ), the macro proceeds differently and does not put stress on the input stack (but is significantly slower for sequences with thousands of integers, especially if they are somewhat big). For example: `\xintSeq [1]{0}{5000}` works and `\xintiiSum{\xintSeq [1]{0}{5000}}` returns the correct value 12502500.

The produced integers are with explicit literal digits, so if used in `\ifnum` or other tests they should be properly terminated<sup>38</sup>.

## 26.11 Completely expandable prime test

Let us now construct a completely expandable macro which returns 1 if its given input is prime and 0 if not:

```
\def\remainder #1#2{\the\numexpr #1-(#1/#2)*#2\relax }
\def\IsPrime #1%
```

This uses `\xintiSqrt` and assumes its input is at least 5. Rather than `xint`'s own `\xintRem` we used a quicker `\numexpr` expression as we are dealing with short integers. Also we used `\xintANDof` which will return 1 only if all the items are non-zero. The macro is a bit silly with an even input, ok, let's enhance it to detect an even input:

```
\def\IsPrime #1%
{\xintifOdd {#1}
  {\xintANDof % odd case
   {\xintApply {\remainder {#1}}{\xintSeq [2]{3}{\xintiSqrt{#1}}}}%
  }%
}%
{\xintifEq {#1}{2}{1}{0}}%
```

We used the `xint` provided expandable tests (on big integers or fractions) in order for `\IsPrime` to be *f*-expandable.

Our integers are short, but without `\expandafter`'s with `\@firstoftwo`, or some other related techniques, direct use of `\ifnum.. \fi` tests is dangerous. So to make the macro more efficient we are going to use the expandable tests provided by the package `etoolbox`<sup>39</sup>. The macro becomes:

```
\def\IsPrime #1%
{\ifnumodd {#1}
  {\xintANDof % odd case
   {\xintApply {\remainder {#1}}{\xintSeq [2]{3}{\xintiSqrt{#1}}}}%
  }%
}%
{\ifnumequal {#1}{2}{1}{0}}}
```

In the odd case however we have to assume the integer is at least 7, as `\xintSeq` generates an empty list if  $#1=3$  or  $5$ , and `\xintANDof` returns 1 when supplied an empty list. Let us ease up a bit `\xintANDof`'s work by letting it work on only 0's and 1's. We could use:

```
\def\ IsNotDivisibleBy #1#2%
{\ifnum\numexpr #1-(#1/#2)*#2=0 \expandafter 0\else \expandafter1\fi}
```

where the `\expandafter`'s are crucial for this macro to be *f*-expandable and hence work within the applied `\xintANDof`. Anyhow, now that we have loaded `etoolbox`, we might as well use:

```
\newcommand{\ IsNotDivisibleBy}[2]{\ifnumequal{#1-(#1/#2)*#2}{0}{1}}
```

Let us enhance our prime macro to work also on the small primes:

---

<sup>38</sup>a `\space` will stop the `TEX` scanning of a number and be gobbled in the process, maintaining expandability if this is required; the `\relax` stops the scanning but is not gobbled and remains afterwards as a token.

<sup>39</sup><http://ctan.org/pkg/etoolbox>

```
\newcommand{\IsPrime}[1] % returns 1 if #1 is prime, and 0 if not
  {\ifnumodd {#1}
    {\ifnumless {#1}{8}
      {\ifnumequal{#1}{1}{0}{1} \% 3,5,7 are primes
       {\xintANDof
         {\xintApply
          { \IsNotDivisibleBy {#1}}{\xintSeq [2]{3}{\xintiSqrt{#1}}}}%
        } \% END OF THE ODD BRANCH
      {\ifnumequal {#1}{2}{1}{0} \% EVEN BRANCH
      }
    }
  }
```

The input is still assumed positive. There is a deliberate blank before `\IsNotDivisibleBy` to use this feature of `\xintApply`: a space stops the expansion of the applied macro (and disappears). This expansion will be done by `\xintANDof`, which has been designed to skip everything as soon as it finds a false (i.e. zero) input. This way, the efficiency is considerably improved.

We did generate via the `\xintSeq` too many potential divisors though. Later sections give two variants: one with `\xintiloop` (subsection 26.14) which is still expandable and another one (subsection 26.21) which is a close variant of the `\IsPrime` code above but with the `\xintFor` loop, thus breaking expandability. The `xintiloop` variant does not first evaluate the integer square root, the `xintFor` variant still does. I did not compare their efficiencies.

Let us construct with this expandable primality test a table of the prime numbers up to 1000. We need to count how many we have in order to know how many tab stops one shoud add in the last row.<sup>40</sup> There is some subtlety for this last row. Turns out to be better to insert a `\\"` only when we know for sure we are starting a new row; this is how we have designed the `\OneCell` macro. And for the last row, there are many ways, we use again `\xintApplyUnbraced` but with a macro which gobbles its argument and replaces it with a tabulation character. The `\xintFor*` macro would be more elegant here.

```
\newcounter{primecount}
\newcounter{cellcount}
\newcommand{\NbOfColumns}{13}
\newcommand{\OneCell}[1]{%
  \ifnumequal{\IsPrime{#1}}{1}
    {\stepcounter{primecount}
     \ifnumequal{\value{cellcount}}{\NbOfColumns}
       {\\\setcounter{cellcount}{1}#1}
       {&\stepcounter{cellcount}#1}%
    } % was prime
  {}% not a prime, nothing to do
}
\newcommand{\OneTab}[1]{&}
\begin{tabular}{|*{\NbOfColumns}{r}|}
\hline
 2 \setcounter{cellcount}{1}\setcounter{primecount}{1}%
   \xintApplyUnbraced \OneCell {\xintSeq [2]{3}{999}}%
   \xintApplyUnbraced \OneTab
   {\xintSeq [1]{1}{\the\numexpr\NbOfColumns-\value{cellcount}\relax}}%
```

---

<sup>40</sup>although a tabular row may have less tabs than in the preamble, there is a problem with the | vertical rule, if one does that.

```
\hline
\end{tabular}
There are \arabic{primecount} prime numbers up to 1000.
```

We had to be careful to use in the last row **\xintSeq** with its optional argument [1] so as to not generate a decreasing sequence from 1 to 0, but really an empty sequence in case the row turns out to already have all its cells (which doesn't happen here but would with a number of columns dividing 168).

|     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 2   | 3   | 5   | 7   | 11  | 13  | 17  | 19  | 23  | 29  | 31  | 37  | 41  |
| 43  | 47  | 53  | 59  | 61  | 67  | 71  | 73  | 79  | 83  | 89  | 97  | 101 |
| 103 | 107 | 109 | 113 | 127 | 131 | 137 | 139 | 149 | 151 | 157 | 163 | 167 |
| 173 | 179 | 181 | 191 | 193 | 197 | 199 | 211 | 223 | 227 | 229 | 233 | 239 |

## 26.12 **\xintloop**, **\xintbreakloop**, **\xintbreakloopanddo**, **\xintloopskiptonext**

- ★ **\xintloop***<stuff>\if<test>...>\repeat* is an expandable loop compatible with nesting. If a sub-loop is to be used all the material from the start and up to the complete subloop inclusive should be braced; these braces will be removed and do not create a group.

As this loop and **\xintiloop** will primarily be of interest to experienced TeX macro programmers, my description will assume that the user is knowledgeable enough. The iterated commands may contain **\par** tokens or empty lines.

One can abort the loop with **\xintbreakloop**; this should not be used in the final test, and one should expand the **\fi** from the corresponding test before. One has also **\xintbreakloopanddo** whose first argument will be inserted in the token stream after the loop; one may need a macro such as **\xint\_afterfi** to move the whole thing after the **\fi**, as a simple **\expandafter** will not be enough.

One will usually employ some count registers to manage the exit test from the loop; this breaks expandability, see **\xintiloop** for an expandable integer indexed loop. Use in alignments will be complicated by the fact that cells create groups, and also from the fact that any encountered unexpandable material will cause the TeX input scanner to insert **\endtemplate** on each encountered & or **\cr**; thus **\xintbreakloop** may not work as expected, but the situation can be resolved via **\xint\_firstofone{&}** or use of **\TAB** with **\def\tAB{&}**. It is thus simpler for alignments to use rather than **\xintloop** either

the expandable `\xintApplyUnbraced` or the non-expandable but alignment compatible `\xintApplyInline`, `\xintFor` or `\xintFor*`.

As an example, let us suppose we have two macros `\A{\langle i \rangle}{\langle j \rangle}` and `\B{\langle i \rangle}{\langle j \rangle}` behaving like (small) integer valued matrix entries, and we want to define a macro `\C{\langle i \rangle}{\langle j \rangle}` giving the matrix product (*i* and *j* may be count registers). We will assume that `\A[I]` expands to the number of rows, `\A[J]` to the number of columns and want the produced `\C` to act in the same manner. The code is very dispendious in use of `\count` registers, not optimized in any way, not made very robust (the defined macro can not have the same name as the first two matrices for example), we just wanted to quickly illustrate use of the nesting capabilities of `\xintloop`.<sup>41</sup>

### 26.13 **\xintiloop**, **\xintiloopindex**, **\xintouteriloopindex**, **\xintbreakiloop**, **\xintbreakiloopanddo**, **\xintiloopskiptonext**, **\xintiloopskipandredo**

- ★ **\xintiloop**[start+delta]<stuff>\if<test> ... \repeat is a completely expandable nestable loop having access via **\xintiloopindex** to the integer index of the iteration, with starting value **start** (which may be a **\count**) and increment **delta** (*id.*). Currently [start+delta] is a *mandatory argument*, it is an error to omit it; perhaps a future release will make it optional with default 1+1. A space after the closing square bracket is not significant, it will be ignored. Spaces inside the square brackets will also be ignored as the two arguments are first given to a **\numexpr... \relax**. Empty lines and explicit **\par** tokens are accepted.

As with **\xintloop**, this tool will mostly be of interest to advanced users. For nesting, one puts inside braces all the material from the start (immediately after [start+delta]) and up to and inclusive of the inner loop, these braces will be removed and do not create

a loop. In case of nesting, `\xintouteriloopindex` gives access to the index of the outer loop. If needed one could write on its model a macro giving access to the index of the outer outer loop (or even to the *n*th outer loop).

The `\xintiloopindex` and `\xintouteriloopindex` can not be used inside braces, and generally speaking this means they should be expanded first when given as argument to a macro, and that this macro receives them as delimited arguments, not braced ones. Or, but naturally this will break expandability, one can assign the value of `\xintiloopindex` to some `\count`. Both `\xintiloopindex` and `\xintouteriloopindex` extend to the litteral representation of the index, thus in `\ifnum` tests, if it comes last one has to correctly end the macro with a `\space`, or encapsulate it in a `\numexpr..\relax`.

When the repeat-test of the loop is, for example, `\ifnum\xintiloopindex<10 \repeat`, this means that the last iteration will be with `\xintiloopindex=10` (assuming `delta=1`). There is also `\ifnum\xintiloopindex=10 \else\repeat` to get the last iteration to be the one with `\xintiloopindex=10`.

One has `\xintbreakiloop` and `\xintbreakiloopanddo` to abort the loop. The syntax of `\xintbreakiloopanddo` is a bit surprising, the sequence of tokens to be executed after breaking the loop is not within braces but is delimited by a dot as in:

```
\xintbreakiloopanddo <afterloop>.etc.. etc... \repeat
```

The reason is that one may wish to use the then current value of `\xintiloopindex` in `<afterloop>` but it can't be within braces at the time it is evaluated. However, it is not that easy as `\xintiloopindex` must be expanded before, so one ends up with code like this:

```
\expandafter\xintbreakiloopanddo\expandafter\macro\xintiloopindex.%  
etc.. etc.. \repeat
```

As moreover the `\fi` from the test leading to the decision of breaking out of the loop must be cleared out of the way, the above should be a branch of an expandable conditional test, else one needs something such as:

```
\xint_afterfi{\expandafter\xintbreakiloopanddo\expandafter\macro\xintiloopindex.%  
 \fi etc..etc.. \repeat}
```

There is `\xintiloopskiponnext` to abort the current iteration and skip to the next, `\xintiloopskipandredo` to skip to the end of the current iteration and redo it with the same value of the index (something else will have to change for this not to become an eternal loop...).

Inside alignments, if the looped-over text contains a `&` or a `\cr`, any un-expandable material before a `\xintiloopindex` will make it fail because of `\endtemplate`; in such cases one can always either replace `&` by a macro expanding to it or replace it by a suitable `\firstofone{&}`, and similarly for `\cr`.

As an example, let us construct an `\edef\z{...}` which will define `\z` to be a list of prime numbers:

```
\edef\z  
{\xintiloop [10001+2]%
```

`\xintiloop [3+2]%`
`\ifnum\xintouteriloopindex<\numexpr\xintiloopindex*\xintiloopindex\relax`
`\xintouteriloopindex,`
`\expandafter\xintbreakiloop`
`\fi`
`\ifnum\xintouteriloopindex=\numexpr`
`(\xintouteriloopindex/\xintiloopindex)*\xintiloopindex\relax`

```
\else
\repeat
}% no space here
\ifnum \xintiloopindex < 10999 \repeat }%

10883, 10889, 10891, 10903, 10909, 10937, 10939, 10949, 10957, 10973, 10979, 10987,
10993, and we should have taken some steps to not have a trailing comma, but the point
was to show that one can do that in an \edef! See also subsection 26.14 which extracts
from this code its way of testing primality.
```

Let us create an alignment where each row will contain all divisors of its first entry.

```
\tabskip1ex
\halign{&\hfil#\hfil\cr
\xintiloop [1+1]
{\expandafter\bfseries\xintiloopindex &
\xintiloop [1+1]
\ifnum\xintouteriloopindex=\numexpr
    (\xintouteriloopindex/\xintiloopindex)*\xintiloopindex\relax
\xintiloopindex&\fi
\ifnum\xintiloopindex<\xintouteriloopindex\space % \space is CRUCIAL
\repeat \cr }%
\ifnum\xintiloopindex<30
\repeat }
```

We wanted this first entry in bold face, but \bfseries leads to unexpandable tokens, so the \expandafter was necessary for \xintiloopindex and \xintouteriloopindex not to be confronted with a hard to digest \endtemplate. An alternative way of coding is:

```
\def\firstofone #1{\#1}%
\halign{&\hfil#\hfil\cr
\xintiloop [1+1]
{\bfseries\xintiloopindex\firstofone{&}%
\xintiloop [1+1] \ifnum\xintouteriloopindex=\numexpr
    (\xintouteriloopindex/\xintiloopindex)*\xintiloopindex\relax
\xintiloopindex\firstofone{&}\fi
\ifnum\xintiloopindex<\xintouteriloopindex\space % \space is CRUCIAL
\repeat \firstofone{\cr}}%
\ifnum\xintiloopindex<30 \repeat }
```

Here is the output, thus obtained without any count register:

|         |             |
|---------|-------------|
| 1 1     | 6 1 2 3 6   |

## 26.14 Another completely expandable prime test

The `\IsPrime` macro from subsection 26.11 checked expandably if a (short) integer was prime, here is a partial rewrite using `\xintiloop`. We use the etoolbox expandable conditionals for convenience, but not everywhere as `\xintiloopindex` can not be evaluated while being braced. This is also the reason why `\xintbreakiloopando` is delimited, and the next macro `\SmallestFactor` which returns the smallest prime factor exemplifies that. One could write more efficient completely expandable routines, the aim here was only to illustrate use of the general purpose `\xintiloop`. A little table giving the first values of `\SmallestFactor` follows, its coding uses `\xintFor`, which is described later; none of this uses count registers.

```
\newcommand{\IsPrime}[1] % returns 1 if #1 is prime, and 0 if not
  {\ifnumodd {#1}
    {\ifnumless {#1}{8}
      {\ifnumequal{#1}{1}{0}{1}}% 3,5,7 are primes
      {\if
        \xintiloop [3+2]
        \ifnum#1<\numexpr\xintiloopindex*\xintiloopindex\relax
          \expandafter\xintbreakiloopando\expandafter1\expandafter.%\fi
        \ifnum#1=\numexpr (#1/\xintiloopindex)*\xintiloopindex\relax
        \else
          \repeat 00\expandafter0\else\expandafter1\fi
        }%
      }%

## 26.15 A table of factorizations

As one more example with `\xintiloop` let us use an alignment to display the factorization of some numbers. The loop will actually only play a minor rôle here, just handling the row index, the row contents being almost entirely produced via a macro `\factorize`. The factorizing macro does not use `\xintiloop` as it didn't appear to be the convenient tool. As `\factorize` will have to be used on `\xintiloopindex`, it has been defined as a delimited macro.

To spare some fractions of a second in the compilation time of this document (which has many many other things to do), 2147483629 and 2147483647, which turn out to be prime numbers, are not given to `factorize` but just typeset directly; this illustrates use of `\xintiloopskeptonext`.

```

\tabskip1ex
\halign {\hfil\strut#\hfil&&\hfil#\hfil\cr\noalign{\hrule}
  \xintiloop ["7FFFFE0+1]
  \expandafter\bf\xintiloopindex &
  \ifnum\xintiloopindex="7FFFFED
    \number"7FFFFED\cr\noalign{\hrule}
    \expandafter\xintiloopskeptonext
\fi

```

```
\expandafter\factorize\xintiloopindex.\cr\noalign{\hrule}
\ifnum\xintiloopindex<"7FFFFFFE
\repeat
\bf \number"7FFFFFFF&\number "7FFFFFFF\cr\noalign{\hrule}
}
```

The **table** has been made into a float which appears on the following page. Here is now the code for factorization; the conditionals use the package provided **\xint\_firstoftwo** and **\xint\_secondeoftwo**, one could have employed rather L<sup>A</sup>T<sub>E</sub>X's own **\@firstoftwo** and **\@secondeoftwo**, or, simpler still in L<sup>A</sup>T<sub>E</sub>X context, the **\ifnumequal**, **\ifnumless** ..., utilities from the package **etoolbox** which do exactly that under the hood. Only T<sub>E</sub>X acceptable numbers are treated here, but it would be easy to make a translation and use the **xint** macros, thus extending the scope to big numbers; naturally up to a cost in speed.

The reason for some strange looking expressions is to avoid arithmetic overflow.

```
\catcode`_ 11
\def\abortfactorize #1\xint_secondeoftwo\fi #2#3{\fi}

\def\factorize #1.{\ifnum#1=1 \abortfactorize\fi
  % avoid overflow if #1="7FFFFFFF
  \ifnum\numexpr #1-2=\numexpr ((#1/2)-1)*2\relax
    \expandafter\xint_firstoftwo
  \else\expandafter\xint_secondeoftwo
  \fi
{2&\expandafter\factorize\the\numexpr#1/2.}%
{\factorize_b #1.3.}}%

\def\factorize_b #1.#2.{\ifnum#1=1 \abortfactorize\fi
  % this will avoid overflow which could result from #2*#2
  \ifnum\numexpr #1-(#2-1)*#2<#2
    #1\abortfactorize % this #1 is prime
  \fi
  % again, avoiding overflow as \numexpr integer division
  % rounds rather than truncates.
  \ifnum \numexpr #1-#2=\numexpr ((#1/#2)-1)*#2\relax
    \expandafter\xint_firstoftwo
  \else\expandafter\xint_secondeoftwo
  \fi
{#2&\expandafter\factorize_b\the\numexpr#1/#2.#2.}%
{\expandafter\factorize_b\the\numexpr #1\expandafter.%
  \the\numexpr #2+2.}}%

\catcode`_ 8
```

The next utilities are not compatible with expansion-only context.

## 26.16 **\xintApplyInline**

*o \*f* **\xintApplyInline{\macro}{\list}** works non expandably. It applies the one-parameter **\macro** to the first element of the expanded list (**\macro** may have itself some arguments,

|                   |            |           |           |         |          |         |        |         |

A table of factorizations

the list item will be appended as last argument), and is then re-inserted in the input stream after the tokens resulting from this first expansion of \macro. The next item is then handled.

This is to be used in situations where one needs to do some repetitive things. It is not expandable and can not be completely expanded inside a macro definition, to prepare material for later execution, contrarily to what \xintApply or \xintApplyUnbraced achieve.

```
\def\Macro #1{\advance\cnta #1 , \the\cnta}
\cnta 0
0\xintApplyInline\Macro {3141592653}. Output: 0, 3, 4, 8, 9, 14, 23, 25, 31, 36, 39.
```

The first argument \macro does not have to be an expandable macro.

\xintApplyInline submits its second, token list parameter to an *f-expansion*. Then, each *unbraced* item will also be *f*-expanded. This provides an easy way to insert one list

inside another. *Braced* items are not expanded. Spaces in-between items are gobbled (as well as those at the start or the end of the list), but not the spaces *inside* the braced items.

`\xintApplyInline`, despite being non-expandable, does survive to contexts where the executed `\macro` closes groups, as happens inside alignments with the tabulation character `&`. This tabular for example:

| $N$ | $N^2$ | $N^3$  |
|-----|-------|--------|
| 17  | 289   | 4913   |
| 28  | 784   | 21952  |
| 39  | 1521  | 59319  |
| 50  | 2500  | 125000 |
| 61  | 3721  | 226981 |

was obtained from the following input:

```
\begin{tabular}{ccc}
$N$ & $N^2$ & $N^3$ \\ \hline
\def\Row #1{ #1 & \xintiSqr {#1} & \xintiPow {#1}{3} \\ \hline }%
\xintApplyInline \Row {\xintCSVtoList{17,28,39,50,61}}
\end{tabular}
```

Despite the fact that the first encountered tabulation character in the first row close a group and thus erases `\Row` from TeX's memory, `\xintApplyInline` knows how to deal with this.

Using `\xintApplyUnbraced` is an alternative: the difference is that this would have prepared all rows first and only put them back into the token stream once they are all assembled, whereas with `\xintApplyInline` each row is constructed and immediately fed back into the token stream: when one does things with numbers having hundreds of digits, one learns that keeping on hold and shuffling around hundreds of tokens has an impact on TeX's speed (make this "thousands of tokens" for the impact to be noticeable).

One may nest various `\xintApplyInline`'s. For example (see the [table](#) on the current page):

```
\def\Row #1{#1:\xintApplyInline {\Item {#1}}{0123456789}\\ }%
\def\Item #1#2{&\xintiPow {#1}{#2}}%
\begin{tabular}{cccccccccc}
&0&1&2&3&4&5&6&7&8&9\\ \hline
0:&1&0&0&0&0&0&0&0&0&0\\
1:&1&1&1&1&1&1&1&1&1&1\\
2:&1&2&4&8&16&32&64&128&256&512\\
3:&1&3&9&27&81&243&729&2187&6561&19683\\
4:&1&4&16&64&256&1024&4096&16384&65536&262144\\
5:&1&5&25&125&625&3125&15625&78125&390625&1953125\\
6:&1&6&36&216&1296&7776&46656&279936&1679616&10077696\\
7:&1&7&49&343&2401&16807&117649&823543&5764801&40353607\\
8:&1&8&64&512&4096&32768&262144&2097152&16777216&134217728\\
9:&1&9&81&729&6561&59049&531441&4782969&43046721&387420489
\end{tabular}
```

|    | 0 | 1 | 2  | 3   | 4    | 5     | 6      | 7       | 8        | 9         |
|----|---|---|----|-----|------|-------|--------|---------|----------|-----------|
| 0: | 1 | 0 | 0  | 0   | 0    | 0     | 0      | 0       | 0        | 0         |
| 1: | 1 | 1 | 1  | 1   | 1    | 1     | 1      | 1       | 1        | 1         |
| 2: | 1 | 2 | 4  | 8   | 16   | 32    | 64     | 128     | 256      | 512       |
| 3: | 1 | 3 | 9  | 27  | 81   | 243   | 729    | 2187    | 6561     | 19683     |
| 4: | 1 | 4 | 16 | 64  | 256  | 1024  | 4096   | 16384   | 65536    | 262144    |
| 5: | 1 | 5 | 25 | 125 | 625  | 3125  | 15625  | 78125   | 390625   | 1953125   |
| 6: | 1 | 6 | 36 | 216 | 1296 | 7776  | 46656  | 279936  | 1679616  | 10077696  |
| 7: | 1 | 7 | 49 | 343 | 2401 | 16807 | 117649 | 823543  | 5764801  | 40353607  |
| 8: | 1 | 8 | 64 | 512 | 4096 | 32768 | 262144 | 2097152 | 16777216 | 134217728 |
| 9: | 1 | 9 | 81 | 729 | 6561 | 59049 | 531441 | 4782969 | 43046721 | 387420489 |

One could not move the definition of `\Item` inside the tabular, as it would get lost after the first &. But this works:

```
\begin{tabular}{cccccccccc}
&0&1&2&3&4&5&6&7&8&9\\ \hline
\def\Row #1{\xintApplyInline {&\xintiPow {#1}}{0123456789}\\\ }%
\xintApplyInline \Row {0123456789}
\end{tabular}
```

A limitation is that, contrarily to what one may have expected, the `\macro` for an `\xintApplyInline` can not be used to define the `\macro` for a nested sub-`\xintApplyInline`. For example, this does not work:

```
\def\Row #1{\def\Item ##1{&\xintiPow {#1}{##1}}%
\xintApplyInline \Item {0123456789}\\\ }%
\xintApplyInline \Row {0123456789} % does not work
```

But see `\xintFor`.

## 26.17 `\xintFor`, `\xintFor*`

*on* `\xintFor` is a new kind of for loop. Rather than using macros for encapsulating list items, its behavior is more like a macro with parameters: #1, #2, ..., #9 are used to represent the items for up to nine levels of nested loops. Here is an example:

```
\xintFor #9 in {1,2,3} \do {%
  \xintFor #1 in {4,5,6} \do {%
    \xintFor #3 in {7,8,9} \do {%
      \xintFor #2 in {10,11,12} \do {%
        $$#9\times#1\times#3\times#2=\xintiiPrd{{#1}{#2}{#3}{#9}}{$$}}}}
```

This example illustrates that one does not have to use #1 as the first one: the order is arbitrary. But each level of nesting should have its specific macro parameter. Nine levels of nesting is presumably overkill, but I did not know where it was reasonable to stop. `\par` tokens are accepted in both the comma separated list and the replacement text.

A macro `\macro` whose definition uses internally an `\xintFor` loop may be used inside another `\xintFor` loop even if the two loops both use the same macro parameter. Note: the loop definition inside `\macro` must double the character # as is the general rule in TeX with definitions done inside macros.

The macros `\xintFor` and `\xintFor*` are not expandable, one can not use them inside an `\edef`. But they may be used inside alignments (such as a L<sup>A</sup>T<sub>E</sub>X `tabular`), as will be shown in examples.

The spaces between the various declarative elements are all optional; furthermore spaces around the commas or at the start and end of the list argument are allowed, they will be removed. If an item must contain itself commas, it should be braced to prevent these commas from being misinterpreted as list separator. These braces will be removed during processing. The list argument may be a macro `\MyList` expanding in one step to the comma separated list (if it has no arguments, it does not have to be braced). It will be expanded (only once) to reveal its comma separated items for processing, comma separated items will not be expanded before being fed into the replacement text as #1, or #2, etc..., only leading and trailing spaces are removed.

*\*fn* A starred variant `\xintFor*` deals with lists of braced items, rather than comma separated items. It has also a distinct expansion policy, which is detailed below.

Contrarily to what happens in loops where the item is represented by a macro, here it is truly exactly as when defining (in L<sup>A</sup>T<sub>E</sub>X) a “command” with parameters #1, etc... This may avoid the user quite a few troubles with `\expandafters` or other `\edef/\noexpand`s which one encounters at times when trying to do things with L<sup>A</sup>T<sub>E</sub>X’s `\@for` or other loops which encapsulate the item in a macro expanding to that item.

The non-starred variant `\xintFor` deals with comma separated values (*spaces before and after the commas are removed*) and the comma separated list may be a macro which is only expanded once (to prevent expansion of the first item `\x` in a list directly input as `\x,\y,\dots` it should be input as `{\x},\y,\dots` or `<space>\x,\y,\dots`, naturally all of that within the mandatory braces of the `\xintFor #n in {list}` syntax). The items are not expanded, if the input is `<stuff>,\x,<stuff>` then #1 will be at some point `\x` not its expansion (and not either a macro with `\x` as replacement text, just the token `\x`). Input such as `<stuff>, ,<stuff>` creates an empty #1, the iteration is not skipped. An empty list does lead to the use of the replacement text, once, with an empty #1 (or #n). Except if the entire list is represented as a single macro with no parameters, `[it must be braced]`.

The starred variant `\xintFor*` deals with token lists (*spaces between braced items or single tokens are not significant*) and `f-expands` each *unbraced* list item. This makes it easy to simulate concatenation of various list macros `\x,\y,\dots`. If `\x` expands to `{1}{2}{3}` and `\y` expands to `{4}{5}{6}` then `{\x\y}` as argument to `\xintFor*` has the same effect as `{1}{2}{3}{4}{5}{6}`<sup>42</sup>. Spaces at the start, end, or in-between items are gobbled (but naturally not the spaces which may be *inside braced items*). Except if the list argument is a single macro with no parameters, `[it must be braced]`. Each item which is not braced will be fully expanded (as the `\x` and `\y` in the example above). An empty list leads to an empty result.

The macro `\xintSeq` which generates arithmetic sequences may only be used with `\xintFor*` (numbers from output of `\xintSeq` are braced, not separated by commas).

`\xintFor* #1 in {\xintSeq [+2]{-7}{+2}}\do {stuff with #1}` will have `#1=-7,-5,-3,-1,` and `1`. The #1 as issued from the list produced by `\xintSeq` is the litteral representation as would be produced by `\arabic` on a L<sup>A</sup>T<sub>E</sub>X counter, it is not a count register. When used in `\ifnum` tests or other contexts where T<sub>E</sub>X looks for a number it should thus be postfix with `\relax` or `\space`.

When nesting `\xintFor*` loops, using `\xintSeq` in the inner loops is inefficient, as the arithmetic sequence will be re-created each time. A more efficient style is:

```
\edef\innersequence {\xintSeq[+2]{-50}{50}}%
\xintFor* #1 in {\xintSeq {13}{27}} \do
  {\xintFor* #2 in \innersequence \do {stuff with #1 and #2}%
   .. some other macros .. }
```

<sup>41</sup>braces around single token items are optional so this is the same as `{123456}`.

This is a general remark applying for any nesting of loops, one should avoid recreating the inner lists of arguments at each iteration of the outer loop. However, in the example above, if the `... some other macros ...` part closes a group which was opened before the `\edef\innersequence`, then this definition will be lost. An alternative to `\edef`, also efficient, exists when dealing with arithmetic sequences: it is to use the `\xintintegers` keyword (described later) which simulates infinite arithmetic sequences; the loops will then be terminated via a test #1 (or #2 etc...) and subsequent use of `\xintBreakFor`.

The `\xintFor` loops are not completely expandable; but they may be nested and used inside alignments or other contexts where the replacement text closes groups. Here is an example (still using L<sup>A</sup>T<sub>E</sub>X's tabular):

|    |                       |                       |                       |                       |                       |
|----|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|
| A: | ( $a \rightarrow A$ ) | ( $b \rightarrow A$ ) | ( $c \rightarrow A$ ) | ( $d \rightarrow A$ ) | ( $e \rightarrow A$ ) |
| B: | ( $a \rightarrow B$ ) | ( $b \rightarrow B$ ) | ( $c \rightarrow B$ ) | ( $d \rightarrow B$ ) | ( $e \rightarrow B$ ) |
| C: | ( $a \rightarrow C$ ) | ( $b \rightarrow C$ ) | ( $c \rightarrow C$ ) | ( $d \rightarrow C$ ) | ( $e \rightarrow C$ ) |

```
\begin{tabular}{rcccc}
\xintFor #7 in {A,B,C} \do {%
    #7:\xintFor* #3 in {abcde} \do {&($ #3 \to #7 $)}\\ }%
\end{tabular}
```

When inserted inside a macro for later execution the # characters must be doubled.<sup>42</sup> For example:

```
\def\T{\def\z {}%
\xintFor* ##1 in {{u}{v}{w}} \do {%
    \xintFor ##2 in {x,y,z} \do {%
        \expandafter\def\expandafter\z\expandafter {\z\sep (##1,##2)} }%
}%
}%
\T\def\sep {\def\sep{, }}\z
(u,x), (u,y), (u,z), (v,x), (v,y), (v,z), (w,x), (w,y), (w,z)
```

Similarly when the replacement text of `\xintFor` defines a macro with parameters, the macro character # must be doubled.

It is licit to use inside an `\xintFor` a `\macro` which itself has been defined to use internally some other `\xintFor`. The same macro parameter #1 can be used with no conflict (as mentioned above, in the definition of `\macro` the # used in the `\xintFor` declaration must be doubled, as is the general rule in T<sub>E</sub>X with things defined inside other things).

The iterated commands as well as the list items are allowed to contain explicit `\par` tokens. Neither `\xintFor` nor `\xintFor*` create groups. The effect is like piling up the iterated commands with each time #1 (or #2 ...) replaced by an item of the list. However, contrarily to the completely expandable `\xintApplyUnbraced`, but similarly to the non completely expandable `\xintApplyInline` each iteration is executed first before looking at the next #1<sup>43</sup> (and the starred variant `\xintFor*` keeps on expanding each unbraced item it finds, gobbling spaces).

---

<sup>42</sup>sometimes what seems to be a macro argument isn't really; in `\raisebox{1cm}{\xintFor #1 in {a,b,c}\do {#1}}` no doubling should be done.

<sup>43</sup>to be completely honest, both `\xintFor` and `\xintFor*` initially scoop up both the list and the iterated commands; `\xintFor` scoops up a second time the entire comma separated list in order to feed it to `\xintCSVtoList`. The starred variant `\xintFor*` which does not need this step will thus be a bit faster on equivalent inputs.

## 26.18 **\xintifForFirst**, **\xintifForLast**

- nn* ★ **\xintifForFirst** {YES branch}{NO branch} and **\xintifForLast** {YES branch}{NO branch} execute the YES or NO branch if the **\xintFor** or **\xintFor\*** loop is currently in its first, respectively last, iteration.

Designed to work as expected under nesting. Don't forget an empty brace pair {} if a branch is to do nothing. May be used multiple times in the replacement text of the loop.

There is no such thing as an iteration counter provided by the **\xintFor** loops; the user is invited to define if needed his own count register or L<sup>A</sup>T<sub>E</sub>X counter, for example with a suitable **\stepcounter** inside the replacement text of the loop to update it.

## 26.19 **\xintBreakFor**, **\xintBreakForAndDo**

One may immediately terminate an **\xintFor** or **\xintFor\*** loop with **\xintBreakFor**. As the criterion for breaking will be decided on a basis of some test, it is recommended to use for this test the syntax of **ifthen**<sup>44</sup> or **etoolbox**<sup>45</sup> or the **xint** own conditionals, rather than one of the various **\if... \fi** of T<sub>E</sub>X. Else (and this is without even mentioning all the various peculiarities of the **\if... \fi** constructs), one has to carefully move the break after the closing of the conditional, typically with **\expandafter\xintBreakFor\fi**.<sup>46</sup>

There is also **\xintBreakForAndDo**. Both are illustrated by various examples in the next section which is devoted to “forever” loops.

## 26.20 **\xintintegers**, **\xintdimensions**, **\xintrationals**

If the list argument to **\xintFor** (or **\xintFor\***, both are equivalent in this context) is **\xintintegers** (equivalently **\xintegers**) or more generally **\xintintegers[start+delta]** (*the whole within braces!*)<sup>47</sup>, then **\xintFor** does an infinite iteration where #1 (or #2, ..., #9) will run through the arithmetic sequence of (short) integers with initial value **start** and increment **delta** (default values: **start=1**, **delta=1**; if the optional argument is present it must contain both of them, and they may be explicit integers, or macros or count registers). The #1 (or #2, ..., #9) will stand for **\numexpr <opt sign><digits>\relax**, and the literal representation as a string of digits can thus be obtained as **\the#1** or **\number#1**. Such a #1 can be used in an **\ifnum** test with no need to be postfix with a space or a **\relax** and one should *not* add them.

If the list argument is **\xintdimensions** or more generally **\xintdimensions[start+delta]** (*within braces!*), then **\xintFor** does an infinite iteration where #1 (or #2, ..., #9) will run through the arithmetic sequence of dimensions with initial value **start** and increment **delta**. Default values: **start=0pt**, **delta=1pt**; if the optional argument is present it must contain both of them, and they may be explicit specifications, or macros, or dimension registers, or length commands in L<sup>A</sup>T<sub>E</sub>X (the stretch and shrink components will be discarded). The #1 will be **\dimexpr <opt sign><digits>sp\relax**, from which one can

---

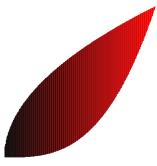

<sup>44</sup><http://ctan.org/pkg/ifthen>

<sup>45</sup><http://ctan.org/pkg/etoolbox>

<sup>46</sup>the difficulties here are similar to those mentioned in [section 13](#), although less severe, as complete expandability is not to be maintained; hence the allowed use of **ifthen**.

<sup>47</sup>the **start+delta** optional specification may have extra spaces around the plus sign of near the square brackets, such spaces are removed. The same applies with **\xintdimensions** and **\xintrationals**.

get the litteral (approximate) representation in points via `\the#1`. So #1 can be used anywhere T<sub>E</sub>X expects a dimension (and there is no need in conditionals to insert a `\relax`, and one should *not* do it), and to print its value one uses `\the#1`. The chosen representation guarantees exact incrementation with no rounding errors accumulating from converting into points at each step.

```
\def\DimToNum #1{\number\dimexpr #1\relax }
\xintNewNumExpr \FA [2] {_DimToNum ${2}^3/{_DimToNum ${1}}^2} % cube
\xintNewNumExpr \FB [2] {sqrt ({_DimToNum ${2}}*{_DimToNum ${1}})} % sqrt
\xintNewExpr \Ratio [2] {trunc({_DimToNum ${2}}/{_DimToNum ${1}},3)}
\xintFor #1 in {\xintdimensions [0pt+.1pt]} \do
{ \ifdim #1>2cm \expandafter\xintBreakFor\fi
{ \color [rgb]{\Ratio {2cm}{#1},0,0}%
\vrule width .1pt height \FB {2cm}{#1}sp depth -\FA {2cm}{#1}sp }%
}% end of For iterated text
```

The **graphic**, with the code on its right<sup>48</sup>, is for illustration only, not only because of pdf rendering artefacts when displaying adjacent rules (which do *not* show in dvi output as rendered by `xdvi`, and depend from your viewer), but because not using anything but rules it is quite inefficient and must do lots of computations to not confer a too ragged look to the borders. With a width of `.5pt` rather than `.1pt` for the rules, one speeds up the drawing by a factor of five, but the boundary is then visibly ragged.<sup>49</sup>

If the list argument to `\xintFor` (or `\xintFor*`) is `\xintrationals` or more generally `\xintrationals[start+delta]` (*within braces!*), then `\xintFor` does an infinite iteration where #1 (or #2, ..., #9) will run through the arithmetic sequence of **xintfrac** fractions with initial value `start` and increment `delta` (default values: `start=1/1`, `delta=1/1`). This loop works *only with xintfrac loaded*. If the optional argument is present it must contain both of them, and they may be given in any of the formats recognized by **xintfrac** (fractions, decimal numbers, numbers in scientific notations, numerators and denominators in scientific notation, etc...), or as macros or count registers (if they are short integers). The #1 (or #2, ..., #9) will be an a/b fraction (without a [n] part), where the denominator b is the product of the denominators of `start` and `delta` (for reasons of speed #1 is not reduced to irreducible form, and for another reason explained later `start` and `delta` are not put either into irreducible form; the input may use explicitly

---

<sup>48</sup>the somewhat peculiar use of `_` and `$` is explained in [subsection 29.6](#); they are made necessary from the fact that the parameters are passed to a *macro* (`\DimToNum`) and not only to *functions*, as are known to `\xintexpr`. But one can also define directly the desired function, for example the constructed `\FA` turns out to have meaning `macro:#1#2->\romannumeral -'0\xintiRound 0{\xintDiv {\xintPow {\DimToNum {#2}}{3}}{\xintPow {\DimToNum {#1}}{2}}}`, where the `\romannumeral` part is only to ensure it expands in only two steps, and could be removed. A handwritten macro would use here `\xintiPow` and not `\xintPow`, as we know it has to deal with integers only. See the next footnote.

<sup>49</sup>to tell the whole truth we cheated and divided by 10 the computation time through using the following definitions, together with a horizontal step of `.25pt` rather than `.1pt`. The displayed original code would make the slowest computation of all those done in this document using the **xint** bundle macros!

```
\def\DimToNum #1{\the\numexpr \dimexpr#1\relax/10000\relax } % no need to be more precise!
\def\FA #1#2{\xintDSH {-4}{\xintQuo {\xintiPow {\DimToNum {#2}}{3}}{\xintiSqr {\DimToNum {#1}}}}}
\def\FB #1#2{\xintDSH {-4}{\xintiSqrt {\xintiMul {\DimToNum {#2}}{\DimToNum {#1}}}}}
\def\Ratio #1#2{\xintTrunc {2}{\DimToNum {#2}/\DimToNum {#1}}}
\xintFor #1 in {\xintdimensions [0pt+.25pt]} \do
{ \ifdim #1>2cm \expandafter\xintBreakFor\fi
{ \color [rgb]{\Ratio {2cm}{#1},0,0}%
\vrule width .25pt height \FB {2cm}{#1}sp depth -\FA {2cm}{#1}sp }%
}% end of For iterated text
```

```
\xintIrr to achieve that.

\xintFor #1 in {\xintrationals [10/21+1/21]} \do
{#1=\xintifInt {#1}
 {\textcolor{blue}{\xintTrunc{10}{#1}}}
 {\xintTrunc{10}{#1}}% in blue if an integer
 \xintifGt {#1}{1.123}{\xintBreakFor}{, }%
}
10/21=0.4761904761, 11/21=0.5238095238, 12/21=0.5714285714, 13/21=0.6190476190,
14/21=0.6666666666, 15/21=0.7142857142, 16/21=0.7619047619, 17/21=0.8095238095,
18/21=0.8571428571, 19/21=0.9047619047, 20/21=0.9523809523, 21/21=1.0000000000,
22/21=1.0476190476, 23/21=1.0952380952, 24/21=1.1428571428
```

The example above confirms that computations are done exactly, and illustrates that the two initial (reduced) denominators are not multiplied when they are found to be equal. It is thus recommended to input `start` and `delta` with a common smallest possible denominator, or as fixed point numbers with the same numbers of digits after the decimal mark; and this is also the reason why `start` and `delta` are not by default made irreducible. As internally the computations are done with numerators and denominators completely expanded, one should be careful not to input numbers in scientific notation with exponents in the hundreds, as they will get converted into as many zeros.

```
\xintFor #1 in {\xintrationals [0.000+0.125]} \do
{\edef\tmp{\xintTrunc{3}{#1}}%
 \xintifInt {#1}
 {\textcolor{blue}{\tmp}}
 {\tmp}%
 \xintifGt {#1}{2}{\xintBreakFor}{, }%
}
0, 0.125, 0.250, 0.375, 0.500, 0.625, 0.750, 0.875, 1.000, 1.125, 1.250,
1.375, 1.500, 1.625, 1.750, 1.875, 2.000, 2.125
```

We see here that `\xintTrunc` outputs (deliberately) zero as 0, not (here) 0.000, the idea being not to lose the information that the truncated thing was truly zero. Perhaps this behavior should be changed? or made optional? Anyhow printing of fixed points numbers should be dealt with via dedicated packages such as `numprint` or `siunitx`.

## 26.21 Another table of primes

As a further example, let us dynamically generate a tabular with the first 50 prime numbers after 12345. First we need a macro to test if a (short) number is prime. Such a completely expandable macro was given in subsection 26.10, here we consider a variant which will be slightly more efficient. This new `\IsPrime` has two parameters. The first one is a macro which it redefines to expand to the result of the primality test applied to the second argument. For convenience we use the `etoolbox` wrappers to various `\ifnum` tests, although here there isn't anymore the constraint of complete expandability (but using explicit `\if.. \fi` in tabulars has its quirks); equivalent tests are provided by `xint`, but they have some overhead as they are able to deal with arbitrarily big integers.

```
\def\IsPrime #1#2% #1=\Result, #2=tested number (assumed >0).
{\edef\TheNumber {\the\numexpr #2}% hence #2 may be a count or \numexpr.
 \ifnumodd {\TheNumber}
 {\ifnumgreater {\TheNumber}{1}
 {\edef\ItsSquareRoot{\xintiSqrt \TheNumber}%
 \xintFor ##1 in {\xintintegers [3+2]}\do
 {\ifnumgreater {##1}{\ItsSquareRoot} % ##1 is a \numexpr.
```

```

{\def#1{1}\xintBreakFor}
{ }%
\ifnumequal {\TheNumber}{(\TheNumber/##1)*##1}
  {\def#1{0}\xintBreakFor }
{ }%
}%
{\def#1{0}}% 1 is not prime
{\ifnumequal {\TheNumber}{2}{\def#1{1}}{\def#1{0}}}}%
}

```

|       |                                            |       |       |       |       |       |
|-------|--------------------------------------------|-------|-------|-------|-------|-------|
| 12347 | 12373                                      | 12377 | 12379 | 12391 | 12401 | 12409 |
| 12413 | 12421                                      | 12433 | 12437 | 12451 | 12457 | 12473 |
| 12479 | 12487                                      | 12491 | 12497 | 12503 | 12511 | 12517 |
| 12527 | 12539                                      | 12541 | 12547 | 12553 | 12569 | 12577 |
| 12583 | 12589                                      | 12601 | 12611 | 12613 | 12619 | 12637 |
| 12641 | 12647                                      | 12653 | 12659 | 12671 | 12689 | 12697 |
| 12703 | 12713                                      | 12721 | 12739 | 12743 | 12757 | 12763 |
| 12781 | These are the first 50 primes after 12345. |       |       |       |       |       |

As we used `\xintFor` inside a macro we had to double the # in its #1 parameter. Here is now the code which creates the prime table (the table has been put in a `float`, which appears above):

```

\newcounter{primecount}
\newcounter{cellcount}
\begin{figure*}[ht!]
  \centering
  \begin{tabular}{|*{7}c|}
    \hline
    \setcounter{primecount}{0}\setcounter{cellcount}{0}%
    \xintFor #1 in {\xintintegers [12345+2]} \do
    % #1 is a \numexpr.
    {\IsPrime\Result{#1}%
     \ifnumgreater{\Result}{0}
     {\stepcounter{primecount}%
      \stepcounter{cellcount}%
      \ifnumequal {\value{cellcount}}{7}
        {\the#1 \\ \setcounter{cellcount}{0}}
        {\the#1 &}}
    }%
    \ifnumequal {\value{primecount}}{50}
      {\xintBreakForAndDo
       {\multicolumn {6}{l}{These are the first 50 primes after 12345.}}\\}
    }%
  \hline
\end{tabular}
\end{figure*}

```

## 26.22 `\xintForpair`, `\xintForthree`, `\xintForfour`

*on* The syntax is illustrated in this example. The notation is the usual one for n-uples, with

parentheses and commas. Spaces around commas and parentheses are ignored.

```
\begin{tabular}{cccc}
  \xintForpair #1#2 in { ( A , a ) , ( B , b ) , ( C , c ) } \do {%
    \xintForpair #3#4 in { ( X , x ) , ( Y , y ) , ( Z , z ) } \do {%
      \$\Biggl( \$\begin{tabular}{cc}
        -#1- & -#3- \\
        -#4- & -#2-
      \end{tabular} \$\Biggr) \$\& } \\ \\ \noalign{\vskip1\jot} } %
\end{tabular}

\begin{array}{ccc}
\left( \begin{array}{cc} -A- & -X- \\ -x- & -a- \end{array} \right) & \left( \begin{array}{cc} -A- & -Y- \\ -y- & -a- \end{array} \right) & \left( \begin{array}{cc} -A- & -Z- \\ -z- & -a- \end{array} \right) \\
\left( \begin{array}{cc} -B- & -X- \\ -x- & -b- \end{array} \right) & \left( \begin{array}{cc} -B- & -Y- \\ -y- & -b- \end{array} \right) & \left( \begin{array}{cc} -B- & -Z- \\ -z- & -b- \end{array} \right) \\
\left( \begin{array}{cc} -C- & -X- \\ -x- & -c- \end{array} \right) & \left( \begin{array}{cc} -C- & -Y- \\ -y- & -c- \end{array} \right) & \left( \begin{array}{cc} -C- & -Z- \\ -z- & -c- \end{array} \right)
\end{array}
```

Only #1#2, #2#3, #3#4, ..., #8#9 are valid (no error check is done on the input syntax, #1#3 or similar all end up in errors). One can nest with `\xintFor`, for disjoint sets of macro parameters. There is also `\xintForthree` (from #1#2#3 to #7#8#9) and `\xintForfour` (from #1#2#3#4 to #6#7#8#9). `\par` tokens are accepted in both the comma separated list and the replacement text.

## 26.23 `\xintAssign`

(*f*→\**x*) \**N* `\xintAssign<braced things>\to<as many cs as they are things>` defines (without checking if something gets overwritten) the control sequences on the right of `\to` to be the complete expansions of the successive braced things found on the left of `\to`. It is not expandable.

A ‘full’ expansion is first applied to the material in front of `\xintAssign`, which may thus be a macro expanding to a list of braced items.

Special case: if after this initial expansion no brace is found immediately after `\xintAssign`, it is assumed that there is only one control sequence following `\to`, and this control sequence is then defined via `\edef` as the complete expansion of the material between `\xintAssign` and `\to`.

```
\xintAssign [oo]\xintDivision{1000000000000}{133333333}\to\Q\R
  \meaning\Q: macro:->7500, \meaning\R: macro:->2500
\xintAssign [oo]\xintiPow {7}{13}\to\SevenToThePowerThirteen
  \SevenToThePowerThirteen=96889010407
```

(same as `\edef\SevenToThePowerThirteen{\xintiPow {7}{13}}`)

New! → `\xintAssign` admits now an optional parameter, for example `\xintAssign [oo]....`. This means that the definitions of the macros initially on the right of `\to` will be made with `\oodef` which expands twice the replacement text. The default is `[e]`, which makes the definitions with `\edef`. Other possibilities: `[]`, `[x]`, `[g]`, `[o]`, `[go]`, `[oo]`, `[goo]`, `[f]`, `[gf]`.

## 26.24 `\xintAssignArray`

(*f*→\**x*) *N* `\xintAssignArray<braced things>\to\myArray` first expands fully what comes immediately after `\xintAssignArray` and expects to find a list of braced things `{A}{B}...` (or

tokens). It then defines `\myArray` as a macro with one parameter, such that `\myArray{x}` expands to give the completely expanded  $x$ th braced thing of this original list (the argument `{x}` itself is fed to a `\numexpr` by `\myArray`, and `\myArray` expands in two steps to its output). With `0` as parameter, `\myArray{0}` returns the number  $M$  of elements of the array so that the successive elements are `\myArray{1}, \dots, \myArray{M}`.

```
\xintAssignArray [oo]\xintBezout {1000}{113}\to\Bez
```

will set `\Bez{0}` to 5, `\Bez{1}` to 1000, `\Bez{2}` to 113, `\Bez{3}` to -20, `\Bez{4}` to -177, and `\Bez{5}` to 1:  $(-20) \times 1000 - (-177) \times 113 = 1$ . This macro is incompatible with expansion-only contexts.

- New! → `\xintAssignArray` admits now an optional parameter, for example `\xintAssignArray [oo]....` This means that the definitions of the macros will be made with `\oodef` (defined *infra*), which expands twice the replacement text. This is more efficient in terms of speed compared to an `\edef`. The default is `[e]`, which makes the definitions with `\edef`. Other possibilities: `[]`, `[o]`, `[oo]`, `[f]`. Contrarily to `\xintAssign` one can not use the `g` here to make the definitions global. For this, one should rather do `\xintAssignArray` within a group starting with `\globaldefs 1`.

## 26.25 `\xintRelaxArray`

- N `\xintRelaxArray\myArray` (globally) sets to `\relax` all macros which were defined by the previous `\xintAssignArray` with `\myArray` as array macro.

## 26.26 `\oodef`, `\oodef`, `\fdef`

- New! → `\oodef\controlsequence {<stuff>} does`  
`\expandafter\expandafter\expandafter\def`  
`\expandafter\expandafter\expandafter\controlsequence`  
`\expandafter\expandafter\expandafter{<stuff>}`

This works only for a single `\controlsequence`, with no parameter text, even without parameters. An alternative would be:

```
\def\oodef #1#{\def\oodefparametertext{#1}%
\expandafter\expandafter\expandafter\expandafter
\expandafter\expandafter\expandafter\def
\expandafter\expandafter\expandafter\oodefparametertext
\expandafter\expandafter\expandafter }
```

but it does not allow `\global` as prefix, and, besides, would have anyhow its use (almost) limited to parameter texts without macro parameter tokens (except if the expanded thing does not see them, or is designed to deal with them).

There is a similar macro `\oodef` with only one expansion of the replacement text `<stuff>`, and `\fdef` which expands fully `<stuff>` using `\romannumeral-'0`.

These tools are provided as it is sometimes wasteful (from the point of view of running time) to do an `\edef` when one knows that the contents expand in only two steps for example, as is the case with all (except `\xintloop` and `\xintiloop`) the expandable macros of the **xint** packages. Each will be defined only if **xinttools** finds them currently undefined. They can be prefixed with `\global`.

## 26.27 The Quick Sort algorithm illustrated

First a completely expandable macro which sorts a list of numbers. The \QSfull macro expands its list argument, which may thus be a macro; its items must expand to possibly big integers (or also decimal numbers or fractions if using **xintfrac**), but if an item is expressed as a computation, this computation will be redone each time the item is considered! If the numbers have many digits (i.e. hundreds of digits...), the expansion of \QSfull is fastest if each number, rather than being explicitly given, is represented as a single token which expands to it in one step.

If the interest is only in **T<sub>E</sub>X** integers, then one should replace the macros \QSMORE, QSEqual, QSLess with versions using the **etoolbox** (**L<sub>A</sub>T<sub>E</sub>X** only) \ifnumgreater, \ifnumequal and \ifnumless conditionals rather than \xintifGt, \xintifEq, \xintifLt.

```
% THE QUICK SORT ALGORITHM EXPANDABLY
\input xintfrac.sty
% HELPER COMPARISON MACROS
\def\QSMORE #1#2{\xintifGt {#2}{#1}{{#2}}{ } }
% the spaces are there to stop the \romannumeral-'0 originating
% in \xintapplyunbraced when it applies a macro to an item

\def\qsfull@e #1#2#3{\expandafter\qsfull@f\expandafter {#2}{#3}{#1}}%
\def\qsfull@f #1#2#3{\expandafter\space #2#1#3}
\makeatother
% EXAMPLE
\edef\z {\QSfull {{1.0}{0.5}{0.3}{1.5}{1.8}{2.0}{1.7}{0.4}{1.2}{1.4}}%
{1.3}{1.1}{0.7}{1.6}{0.6}{0.9}{0.8}{0.2}{0.1}{1.9}}%
\tt\meaning\z
\def\aa {3.123456789123456789}\def\bb {3.123456789123456788}
```

```
\def\c {3.123456789123456790}\def\d {3.123456789123456787}
\expandafter\def\expandafter\z\expandafter
  {\romannumeral0\qfull {{\a}\b\c\!d}}% \a is braced to not be expanded
\meaning\z
```

Output:

```
macro:->{0.1}{0.2}{0.3}{0.4}{0.5}{0.6}{0.7}{0.8}{0.9}{1.0}{1.1}{1.2}{1.3}{1.4}{1.5}{1.6}{1.7}{1.8}{1.9}{2.0}
macro:->{\d}{\b}{\a}{\c}
```

We then turn to a graphical illustration of the algorithm. For simplicity the pivot is always chosen to be the first list item. We also show later how to illustrate the variant which picks up the last item of each unsorted chunk as pivot.

```

| 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 | 1.6 | 1.7 | 1.8 | 1.9 | 2.0 |
| 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 | 1.0 | 1.1 | 1.2 | 1.3 | 1.4 | 1.5 | 1.6 | 1.7 | 1.8 | 1.9 | 2.0 |

It is possible to modify this code to let it do `\QSonestep` repeatedly and stop automatically when the sort is finished.<sup>50</sup>

<sup>50</sup><http://tex.stackexchange.com/a/142634/4686>

## 27 Commands of the **xint** package

In the description of the macros {N} and {M} stand for (long) numbers within braces or for a control sequence possibly within braces and *f-expanding* to such a number (without the braces!), or for material within braces which *f*-expands to such a number, as is acceptable on input by the `\xintNum` macro: a sequence of plus and minus signs, followed by some string of zeros, followed by digits. The margin annotation for such an argument which is parsed by `\xintNum` is  $\frac{\text{Num}}{f}$ . Sometimes however only a *f* symbol appears in the margin, signaling that the input will not be parsed via `\xintNum`.

The letter *x* (with margin annotation  $\frac{\text{num}}{x}$ ) stands for something which will be inserted in-between a `\numexpr` and a `\relax`. It will thus be completely expanded and must give an integer obeying the *TEX* bounds. Thus, it may be for example a count register, or itself a `\numexpr` expression, or just a number written explicitly with digits or something like `4*\count 255 + 17`, etc...

For the rules regarding direct use of count registers or `\numexpr` expression, in the argument to the package macros, see the [Use of count](#) section.

Some of these macros are extended by **xintfrac** to accept fractions on input, and, generally, to output a fraction. But this means that additions, subtractions, multiplications output in fraction format; to guarantee the integer format on output when the inputs are integers, the original integer-only macros `\xintAdd`, `\xintSub`, `\xintMul`, etc... are available under the names `\xintiAdd`, `\xintiSub`, `\xintiMul`, ..., also when **xintfrac** is not loaded. Even these originally integer-only macros will accept fractions on input if **xintfrac** is loaded as long as they are integers in disguise; they produce on output integers without any forward slash mark nor trailing [n].

But `\xintAdd` will output fractions A/B[n], with B present even if its value is one. See the [xintfrac documentation](#) for additional information.

## 27.1 \xintRev

*f★* `\xintRev{N}` will revert the order of the digits of the number, keeping the optional sign. Leading zeros resulting from the operation are not removed (see the `\xintNum` macro for this). This macro and all other macros dealing with numbers first expand ‘fully’ their arguments.

```
\xintRev{-123000}=-000321
\xintNum{\xintRev{-123000}}=-321
```

## 27.2 \xintLen

*Num f★* `\xintLen{N}` returns the length of the number, not counting the sign.

```
\xintLen{-12345678901234567890123456789}=29
```

Extended by `xintfrac` to fractions: the length of  $A/B[n]$  is the length of  $A$  plus the length of  $B$  plus the absolute value of  $n$  and minus one (an integer input as  $N$  is internally represented in a form equivalent to  $N/1[0]$  so the minus one means that the extended `\xintLen` behaves the same as the original for integers).

```
\xintLen{-1e3/5.425}=10
```

The length is computed on the  $A/B[n]$  which would have been returned by `\xintRaw`:  
`\xintRaw {-1e3/5.425}=-1/5425[6]`.

Let’s point out that the whole thing should sum up to less than circa  $2^{31}$ , but this is a bit theoretical.

`\xintLen` is only for numbers or fractions. See `\xintLength` for counting tokens (or rather braced groups), more generally.

## 27.3 \xintDigitsOf

*fN* This is a synonym for `\xintAssignArray`, to be used to define an array giving all the digits of a given (positive, else the minus sign will be treated as first item) number.

```
\xintDigitsOf\xintiPow {7}{500}\to\digits
```

$7^{500}$  has  $\text{\texttt{digits}}\{0\}=423$  digits, and the 123rd among them (starting from the most significant) is  $\text{\texttt{digits}}\{123\}=3$ .

## 27.4 **\xintNum**

- f* ★  $\text{\texttt{xintNum}}\{N\}$  removes chains of plus or minus signs, followed by zeros.  
 $\text{\texttt{xintNum}}\{+----+---000000000367941789479\}=-367941789479$   
 Extended by **xintfrac** to accept also a fraction on input, as long as it reduces to an integer after division of the numerator by the denominator.  
 $\text{\texttt{xintNum}}\{123.48/-0.03\}=-4116$

## 27.5 **\xintSgn**

- Num f* ★  $\text{\texttt{xintSgn}}\{N\}$  returns 1 if the number is positive, 0 if it is zero and -1 if it is negative.  
*f* ★ Extended by **xintfrac** to fractions. **\xintiiSgn** skips the **\xintNum** overhead.

## 27.6 **\xintOpp**

- Num f* ★  $\text{\texttt{xintOpp}}\{N\}$  return the opposite  $-N$  of the number  $N$ . Extended by **xintfrac** to fractions.  
 $\text{\texttt{xintiOpp}}$  is a synonym not modified by **xintfrac**<sup>51</sup>, and  $\text{\texttt{xintiiOpp}}$  skips the **\xintNum** overhead.

## 27.7 **\xintAbs**

- Num f* ★  $\text{\texttt{xintAbs}}\{N\}$  returns the absolute value of the number. Extended by **xintfrac** to fractions.  
 $\text{\texttt{xintiAbs}}$  is a synonym not modified by **xintfrac**, and  $\text{\texttt{xintiiAbs}}$  skips the **\xintNum** overhead.

## 27.8 **\xintAdd**

- Num Num f f* ★  $\text{\texttt{xintAdd}}\{N\}\{M\}$  returns the sum of the two numbers. Extended by **xintfrac** to fractions.  
 $\text{\texttt{xintiAdd}}$  is a synonym not modified by **xintfrac**, and  $\text{\texttt{xintiiAdd}}$  skips the **\xintNum** overhead.

## 27.9 **\xintSub**

- Num Num f f* ★  $\text{\texttt{xintSub}}\{N\}\{M\}$  returns the difference  $N-M$ . Extended by **xintfrac** to fractions.  $\text{\texttt{xintiSub}}$  is a synonym not modified by **xintfrac**, and  $\text{\texttt{xintiiSub}}$  skips the **\xintNum** overhead.

## 27.10 **\xintCmp**

- Num Num f f* ★  $\text{\texttt{xintCmp}}\{N\}\{M\}$  returns 1 if  $N>M$ , 0 if  $N=M$ , and -1 if  $N<M$ . Extended by **xintfrac** to fractions.

## 27.11 **\xintEq**

- Num Num f f* ★  $\text{\texttt{xintEq}}\{N\}\{M\}$  returns 1 if  $N=M$ , 0 otherwise. Extended by **xintfrac** to fractions.

---

<sup>51</sup>here, and in all similar instances, this means that the macro remains integer-only both on input and output, but it does accept on input a fraction which in disguise is a (big) integer.

**27.12 \xintGt**

$f^{\text{Num}} f^{\text{Num}}$  ★  $\backslash\xintGt\{N\}\{M\}$  returns 1 if  $N > M$ , 0 otherwise. Extended by **xintfrac** to fractions.

**27.13 \xintLt**

$f^{\text{Num}} f^{\text{Num}}$  ★  $\backslash\xintLt\{N\}\{M\}$  returns 1 if  $N < M$ , 0 otherwise. Extended by **xintfrac** to fractions.

**27.14 \xintIsZero**

$f^{\text{Num}}$  ★  $\backslash\xintIsZero\{N\}$  returns 1 if  $N = 0$ , 0 otherwise. Extended by **xintfrac** to fractions.

**27.15 \xintNot**

$f^{\text{Num}}$  ★  $\backslash\xintNot$  is a synonym for  $\backslash\xintIsZero$ .

**27.16 \xintIsNotZero**

$f^{\text{Num}}$  ★  $\backslash\xintIsNotZero\{N\}$  returns 1 if  $N \neq 0$ , 0 otherwise. Extended by **xintfrac** to fractions.

**27.17 \xintIsOne**

$f^{\text{Num}}$  ★  $\backslash\xintIsOne\{N\}$  returns 1 if  $N = 1$ , 0 otherwise. Extended by **xintfrac** to fractions.

**27.18 \xintAND**

$f^{\text{Num}} f^{\text{Num}}$  ★  $\backslash\xintAND\{N\}\{M\}$  returns 1 if  $N \neq 0$  and  $M \neq 0$  and zero otherwise. Extended by **xintfrac** to fractions.

**27.19 \xintOR**

$f^{\text{Num}} f^{\text{Num}}$  ★  $\backslash\xintOR\{N\}\{M\}$  returns 1 if  $N \neq 0$  or  $M \neq 0$  and zero otherwise. Extended by **xintfrac** to fractions.

**27.20 \xintXOR**

$f^{\text{Num}} f^{\text{Num}}$  ★  $\backslash\xintXOR\{N\}\{M\}$  returns 1 if exactly one of  $N$  or  $M$  is true (i.e. non-zero). Extended by **xintfrac** to fractions.

**27.21 \xintANDof**

$f \rightarrow * f^{\text{Num}}$  ★  $\backslash\xintANDof\{\{a\}\{b\}\{c\} \dots\}$  returns 1 if all are true (i.e. non zero) and zero otherwise. The list argument may be a macro, it (or rather its first token) is  $f$ -expanded first (each item also is  $f$ -expanded). Extended by **xintfrac** to fractions.

**27.22 \xintORof**

$f \rightarrow * f^{\text{Num}}$  ★  $\backslash\xintORof\{\{a\}\{b\}\{c\} \dots\}$  returns 1 if at least one is true (i.e. does not vanish). The list argument may be a macro, it is  $f$ -expanded first. Extended by **xintfrac** to fractions.

**27.23 \xintXORof**

- $f \rightarrow *^{\text{Num}} f$  ★  $\text{\xintXORof}\{\{a\}{b\}c\}\dots\}$  returns 1 if an odd number of them are true (i.e. does not vanish). The list argument may be a macro, it is  $f$ -expanded first. Extended by **xintfrac** to fractions.

**27.24 \xintGeq**

- $f \rightarrow *^{\text{Num}} f$  ★  $\text{\xintGeq}\{N\}M$  returns 1 if the *absolute value* of the first number is at least equal to the absolute value of the second number. If  $|N| < |M|$  it returns 0. Extended by **xintfrac** to fractions. Please note that the macro compares *absolute values*.

**27.25 \xintMax**

- $f \rightarrow *^{\text{Num}} f$  ★  $\text{\xintMax}\{N\}M$  returns the largest of the two in the sense of the order structure on the relative integers (*i.e.* the right-most number if they are put on a line with positive numbers on the right):  $\text{\xintiMax}\{-5\}{-6}=-5$ . Extended by **xintfrac** to fractions.  $\text{\xintiMax}$  is a synonym not modified by **xintfrac**.

**27.26 \xintMaxof**

- $f \rightarrow *^{\text{Num}} f$  ★  $\text{\xintMaxof}\{\{a\}{b\}c\}\dots\}$  returns the maximum. The list argument may be a macro, it is  $f$ -expanded first. Extended by **xintfrac** to fractions.  $\text{\xintiMaxof}$  is a synonym not modified by **xintfrac**.

**27.27 \xintMin**

- $f \rightarrow *^{\text{Num}} f$  ★  $\text{\xintMin}\{N\}M$  returns the smallest of the two in the sense of the order structure on the relative integers (*i.e.* the left-most number if they are put on a line with positive numbers on the right):  $\text{\xintiMin}\{-5\}{-6}=-6$ . Extended by **xintfrac** to fractions.  $\text{\xintiMin}$  is a synonym not modified by **xintfrac**.

**27.28 \xintMinof**

- $f \rightarrow *^{\text{Num}} f$  ★  $\text{\xintMinof}\{\{a\}{b\}c\}\dots\}$  returns the minimum. The list argument may be a macro, it is  $f$ -expanded first. Extended by **xintfrac** to fractions.  $\text{\xintiMinof}$  is a synonym not modified by **xintfrac**.

**27.29 \xintSum**

- \*f ★  $\text{\xintSum}\{\langle braced\ things\rangle\}$  after expanding its argument expects to find a sequence of tokens (or braced material). Each is expanded (with the usual meaning), and the sum of all these numbers is returned. Note: the summands are *not* parsed by **\xintNum**.

$\text{\xintSum}$  is extended by **xintfrac** to fractions. The original, which accepts (after  $f$ -expansion) only (big) integers in the strict format and produces a (big) integer is available as  $\text{\xintiiSum}$ , also with **xintfrac** loaded.

```
\xintiiSum{{123}{-98763450}{\xintFac{7}}{\xintiMul{3347}{591}}}=-96780210
\xintiiSum{1234567890}=45
```

An empty sum is no error and returns zero: `\xintiiSum {}=0`. A sum with only one term returns that number: `\xintiiSum {{-1234}}=-1234`. Attention that `\xintiiSum {-1234}` is not legal input and will make the TeX run fail. On the other hand `\xintiiSum {1234}=10`. Extended by **xintfrac** to fractions.

### 27.30 **\xintMul**

- Num Num  $f f$  ★ `\xintMul{N}{M}` returns the product of the two numbers. Extended by **xintfrac** to fractions. `\xintiMul` is a synonym not modified by **xintfrac**, and `\xintiiMul` skips the `\xintNum` overhead.
- ff ★ `\xintNum`

### 27.31 **\xintSqr**

- Num  $f$  ★ `\xintSqr{N}` returns the square. Extended by **xintfrac** to fractions. `\xintiSqr` is a synonym not modified by **xintfrac**, and `\xintiiSqr` skips the `\xintNum` overhead.

### 27.32 **\xintPrd**

- \*f ★ `\xintPrd{{braced things}}` after expanding its argument expects to find a sequence of (of braced items or unbraced single tokens). Each is expanded (with the usual meaning), and the product of all these numbers is returned. Note: the operands are *not* parsed by **\xintNum**.

```
\xintiiPrd{{-9876}}{\xintFac{7}}{\xintiMul{3347}{591}}=-98458861798080
\xintiiPrd{123456789123456789}=131681894400
```

An empty product is no error and returns 1: `\xintiiPrd {}=1`. A product reduced to a single term returns this number: `\xintiiPrd {{-1234}}=-1234`. Attention that `\xintiPrd {-1234}` is not legal input and will make the TeX compilation fail. On the other hand `\xintiiPrd {1234}=24`.

$2^{200}3^{100}7^{100}$

```
=\xintiiPrd {{\xintiPow{2}{200}}{\xintiPow{3}{100}}{\xintiPow{7}{100}}}
=26787279316615775757662795170075484023247402663740153489744596148
154264129654994900004440072407657271300001653120764065456211801435
71994015903343539244028212438966822248927862988084382716133376 With
xintexpr, the above would be coded simply as
```

```
\xinttheiexpr 2^200*3^100*7^100\relax
```

Extended by **xintfrac** to fractions. The original, which accepts (after *f*-expansion) only (big) integers in the strict format and produces a (big) integer is available as `\xintiiPrd`, also with **xintfrac** loaded.

### 27.33 **\xintPow**

- Num num  $f x$  ★ `\xintPow{N}{x}` returns  $N^x$ . When  $x$  is zero, this is 1. If  $N$  is zero and  $x < 0$ , if  $|N| > 1$  and  $x < 0$  negative, or if  $|N| > 1$  and  $x > 999999999$ , then an error is raised.  $2^{999999999}$  has 301,029,996 digits; each exact multiplication of two one thousand digits numbers already takes a few seconds, so needless to say this bound is completely unrealistic. Already  $2^{9999}$  has 3,010 digits,<sup>52</sup> so I should perhaps lower the bound to 99999.

<sup>52</sup>on my laptop `\xintiPow{2}{9999}` obtains all 3010 digits in about ten or eleven seconds. In contrast, the float versions for 8, 16, 24, or even more significant figures, do their jobs in circa one hundredth of

Extended by **xintfrac** to fractions (`\xintPow`) and to floats (`\xintFloatPow`). Negative exponents do not then cause errors anymore. The float version is able to deal with things such as  $2^{999999999}$  without any problem. For example `\xintFloatPow[4]{2}{9999}=9.975e3009` and `\xintFloatPow[4]{2}{999999999}=2.306e301029995`.

$f_x^{\text{num}}$  ★ `\xintiPow` is a synonym not modified by **xintfrac**, and `\xintiiPow` is an integer only variant skipping the `\xintNum` overhead.

### 27.34 `\xintSgnFork`

$x nnn$  ★ `\xintSgnFork{-1|0|1}{⟨A⟩}{⟨B⟩}{⟨C⟩}` expandably chooses to execute either the ⟨A⟩, ⟨B⟩ or ⟨C⟩ code, depending on its first argument. This first argument should be anything expanding to either -1, 0 or 1 (a count register must be prefixed by `\the` and a `\numexpr... \relax` also must be prefixed by `\the`). This utility is provided to help construct expandable macros choosing depending on a condition which one of the package macros to use, or which values to confer to their arguments.

### 27.35 `\xintifSgn`

$f_{\text{Num}} nnn$  ★ Similar to `\xintSgnFork` except that the first argument may expand to a (big) integer (or a fraction if **xintfrac** is loaded), and it is its sign which decides which of the three branches is taken. Furthermore this first argument may be a count register, with no `\the` or `\number` prefix.

### 27.36 `\xintifZero`

$f_{\text{Num}} nn$  ★ `\xintifZero{⟨N⟩}{⟨IsZero⟩}{⟨IsNotZero⟩}` expandably checks if the first mandatory argument N (a number, possibly a fraction if **xintfrac** is loaded, or a macro expanding to one such) is zero or not. It then either executes the first or the second branch. Beware that both branches must be present.

### 27.37 `\xintifNotZero`

$f_{\text{Num}} nn$  ★ `\xintifNotZero{⟨N⟩}{⟨IsNotZero⟩}{⟨IsZero⟩}` expandably checks if the first mandatory argument N (a number, possibly a fraction if **xintfrac** is loaded, or a macro expanding to one such) is not zero or is zero. It then either executes the first or the second branch. Beware that both branches must be present.

### 27.38 `\xintifOne`

$f_{\text{Num}} nn$  ★ `\xintifOne{⟨N⟩}{⟨IsOne⟩}{⟨IsNotOne⟩}` expandably checks if the first mandatory argument N (a number, possibly a fraction if **xintfrac** is loaded, or a macro expanding to one such) is one or not. It then either executes the first or the second branch. Beware that both branches must be present.

---

a second (1.08b). This is done without `log/exp` which are not (yet?) implemented in **xintfrac**. The `LATEX3 l3fp` does this with `log/exp` and is ten times faster (16 figures only).

**27.39 \xintifTrueAelseB, \xintifFalseAelseB**

Num  $f\ nn$  ★  $\xintifTrueAelseB{\langle N \rangle}{\langle true\ branch \rangle}{\langle false\ branch \rangle}$  is a synonym for  $\xintifNotZero$ .

1. with 1.09i, the synonyms  $\xintifTrueFalse$  and  $\xintifTrue$  are deprecated and will be removed in next release.

2. These macros have no lowercase versions, use  $\xintifzero$ ,  $\xintifnotzero$ .

Num  $f\ nn$  ★  $\xintifFalseAelseB{\langle N \rangle}{\langle false\ branch \rangle}{\langle true\ branch \rangle}$  is a synonym for  $\xintifZero$ .

**27.40 \xintifCmp**

Num Num  $f\ f\ nnn$  ★  $\xintifCmp{\langle A \rangle}{\langle B \rangle}{\langle if\ A < B \rangle}{\langle if\ A = B \rangle}{\langle if\ A > B \rangle}$  compares its arguments and chooses accordingly the correct branch.

**27.41 \xintifEq**

Num Num  $f\ f\ nn$  ★  $\xintifEq{\langle A \rangle}{\langle B \rangle}{\langle YES \rangle}{\langle NO \rangle}$  checks equality of its two first arguments (numbers, or fractions if **xintfrac** is loaded) and does the YES or the NO branch.

**27.42 \xintifGt**

Num Num  $f\ f\ nn$  ★  $\xintifGt{\langle A \rangle}{\langle B \rangle}{\langle YES \rangle}{\langle NO \rangle}$  checks if  $A > B$  and in that case executes the YES branch. Extended to fractions (in particular decimal numbers) by **xintfrac**.

**27.43 \xintifLt**

Num Num  $f\ f\ nn$  ★  $\xintifLt{\langle A \rangle}{\langle B \rangle}{\langle YES \rangle}{\langle NO \rangle}$  checks if  $A < B$  and in that case executes the YES branch. Extended to fractions (in particular decimal numbers) by **xintfrac**.

The macros described next are all integer-only on input. With **xintfrac** loaded their argument is first given to **\xintNum** and may thus be a fraction, as long as it is in fact an integer in disguise.

**27.44 \xintifOdd**

Num  $f\ nn$  ★  $\xintifOdd{\langle A \rangle}{\langle YES \rangle}{\langle NO \rangle}$  checks if  $A$  is an odd integer and in that case executes the YES branch.

**27.45 \xintFac**

num  $x$  ★  $\xintFac{x}$  returns the factorial. It is an error if the argument is negative or at least  $10^6$ .

With **xintfrac** loaded, the macro is modified to accept a fraction as argument, as long as this fraction turns out to be an integer:  $\xintFac{66/3}=1124000727777607680000$ . **\xintiFac** is a synonym not modified by the loading of **xintfrac**.

### 27.46 \xintDivision

- Num Num
- f f ★  $\backslash\xintDivision{N}{M}$  returns {quotient Q}{remainder R}. This is euclidean division:  $N = QM + R$ ,  $0 \leq R < |M|$ . So the remainder is always non-negative and the formula  $N = QM + R$  always holds independently of the signs of N or M. Division by zero is an error (even if N vanishes) and returns {0}{0}. The variant  $\backslash\xintiiDivision$  skips the overhead of parsing via  $\backslash\xintNum$ .
  - ff ★ The macro is integer only (with **xintfrac** loaded it accepts fractions on input, but they must be integers in disguise) and not to be confused with the **xintfrac** macro  $\backslash\xintDiv$  which divides one fraction by another.

### 27.47 \xintQuo

- Num Num
- f f ★  $\backslash\xintQuo{N}{M}$  returns the quotient from the euclidean division. When both N and M are positive one has  $\backslash\xintQuo{N}{M}=\backslash\xintiTrunc{0}{N/M}$  (using package **xintfrac**). With **xintfrac** loaded it accepts fractions on input, but they must be integers in disguise.
  - ff ★ The variant  $\backslash\xintiiQuo$  skips the overhead of parsing via  $\backslash\xintNum$ .

### 27.48 \xintRem

- Num Num
- f f ★  $\backslash\xintRem{N}{M}$  returns the remainder from the euclidean division. With **xintfrac** loaded it accepts fractions on input, but they must be integers in disguise. The variant  $\backslash\xintiiRem$  skips the overhead of parsing via  $\backslash\xintNum$ .

### 27.49 \xintFDg

- Num
- f ★  $\backslash\xintFDg{N}$  returns the first digit (most significant) of the decimal expansion. The variant  $\backslash\xintiiFDg$  skips the overhead of parsing via  $\backslash\xintNum$ .

### 27.50 \xintLDg

- Num
- f ★  $\backslash\xintLDg{N}$  returns the least significant digit. When the number is positive, this is the same as the remainder in the euclidean division by ten. The variant  $\backslash\xintiiLDg$  skips the overhead of parsing via  $\backslash\xintNum$ .

### 27.51 \xintMON, \xintMMON

- Num
- f ★  $\backslash\xintMON{N}$  returns  $(-1)^N$  and  $\backslash\xintMMON{N}$  returns  $(-1)^{N-1}$ .  

$$\backslash\xintMON{-280914019374101929}=-1, \backslash\xintMMON{-280914019374101929}=1$$
  - f ★ The variants  $\backslash\xintiiMON$  and  $\backslash\xintiiMMON$  skip the overhead of parsing via  $\backslash\xintNum$ .

### 27.52 \xintOdd

- Num
- f ★  $\backslash\xintOdd{N}$  is 1 if the number is odd and 0 otherwise. The variant  $\backslash\xintiiOdd$  skip the overhead of parsing via  $\backslash\xintNum$ .

### 27.53 **\xintiSqrt**, **\xintiSquareRoot**

- Num f ★  $\backslash\xintiSqrt{N}$  returns the largest integer whose square is at most equal to N.
- ```
\xintiSqrt {20000000000000000000000000000000}=1414213562373095048
\xintiSqrt {30000000000000000000000000000000}=1732050807568877293
\xintiSqrt {\xintDSH {-120}{2}}=
1414213562373095048801688724209698078569671875376948073176679
```
- Num f ★  $\backslash\xintiSquareRoot{N}$  returns  $\{M\}\{d\}$  with  $d > 0$ ,  $M^2 - d = N$  and M smallest (hence  $= 1 + \xintiSqrt{N}$ ).
- ```
\xintAssign\xintiSquareRoot {17000000000000000000000000}\to\A\B
\xintiSub{\xintiSqr{\A}}{\B}=\A^2-\B
170000000000000000000000=4123105625618^2-2799177881924
```
- A rational approximation to  $\sqrt{N}$  is  $M - \frac{d}{2M}$  (this is a majorant and the error is at most  $1/2M$ ; if N is a perfect square  $k^2$  then  $M=k+1$  and this gives  $k+1/(2k+2)$ , not k).
- Package **xintfrac** has **\xintFloatSqrt** for square roots of floating point numbers.

The macros described next are strictly for integer-only arguments. These arguments are *not* filtered via **\xintNum**.

### 27.54 **\xintInc**, **\xintDec**

- f ★  $\backslash\xintInc{N}$  is  $N+1$  and  $\backslash\xintDec{N}$  is  $N-1$ . These macros remain integer-only, even with **xintfrac** loaded.

### 27.55 **\xintDouble**, **\xintHalf**

- f ★  $\backslash\xintDouble{N}$  returns  $2N$  and  $\backslash\xintHalf{N}$  is  $N/2$  rounded towards zero. These macros remain integer-only, even with **xintfrac** loaded.

### 27.56 **\xintDSL**

- f ★  $\backslash\xintDSL{N}$  is decimal shift left, *i.e.* multiplication by ten.

### 27.57 **\xintDSR**

- f ★  $\backslash\xintDSR{N}$  is decimal shift right, *i.e.* it removes the last digit (keeping the sign), equivalently it is the closest integer to  $N/10$  when starting at zero.

### 27.58 **\xintDSH**

- num f ★  $\backslash\xintDSH{x}{N}$  is parametrized decimal shift. When x is negative, it is like iterating  $\backslash\xintDSL{|x|}$  times (*i.e.* multiplication by  $10^{-\{-x\}}$ ). When x positive, it is like iterating  $\backslash\xintDSR{x}$  times (and is more efficient), and for a non-negative N this is thus the same as the quotient from the euclidean division by  $10^x$ .

### 27.59 \xintDSHr, \xintDSx

**num** *x f* ★  $\backslash\xintDSHr{x}{N}$  expects *x* to be zero or positive and it returns then a value *R* which is correlated to the value *Q* returned by  $\backslash\xintDSH{x}{N}$  in the following manner:

- if *N* is positive or zero, *Q* and *R* are the quotient and remainder in the euclidean division by  $10^{|x|}$  (obtained in a more efficient manner than using  $\backslash\xintDivision$ ),
- if *N* is negative let *Q1* and *R1* be the quotient and remainder in the euclidean division by  $10^{|x|}$  of the absolute value of *N*. If *Q1* does not vanish, then *Q*=-*Q1* and *R*=*R1*. If *Q1* vanishes, then *Q*=0 and *R*=-*R1*.
- for *x*=0, *Q*=*N* and *R*=0.

So one has  $N = 10^{|x|} Q + R$  if *Q* turns out to be zero or positive, and  $N = 10^{|x|} Q - R$  if *Q* turns out to be negative, which is exactly the case when *N* is at most  $-10^{|x|}$ .

**num** *x f* ★  $\backslash\xintDSx{x}{N}$  for *x* negative is exactly as  $\backslash\xintDSH{x}{N}$ , i.e. multiplication by  $10^{-|x|}$ . For *x* zero or positive it returns the two numbers {*Q*}{*R*} described above, each one within braces. So *Q* is  $\backslash\xintDSH{x}{N}$ , and *R* is  $\backslash\xintDSHr{x}{N}$ , but computed simultaneously.

\xintDSH {9}{-123004321}=0, \xintDSHr {9}{-123004321}=-123004321
```

### 27.60 \xintDecSplit

**num** *x f* ★  $\backslash\xintDecSplit{x}{N}$  cuts the number into two pieces (each one within a pair of enclosing braces). First the sign if present is *removed*. Then, for *x* positive or null, the second piece contains the *x* least significant digits (*empty* if *x*=0) and the first piece the remaining digits (*empty* when *x* equals or exceeds the length of *N*). Leading zeros in the second piece are not removed. When *x* is negative the first piece contains the  $|x|$  most significant digits and the second piece the remaining digits (*empty* if  $|x|$  equals or exceeds the length of *N*). Leading zeros in this second piece are not removed. So the absolute value of the original number is always the concatenation of the first and second piece.

This macro's behavior for *N* non-negative is final and will not change. I am still hesitant about what to do with the sign of a negative *N*.

\meaning\L: macro:->12300004321, \meaning\R: macro:->.
```

## 27.61 **\xintDecSplitL**

$\text{num}_x f$  ★ `\xintDecSplitL{x}{N}` returns the first piece after the action of `\xintDecSplit`.

## 27.62 **\xintDecSplitR**

$\text{num}_x f$  ★ `\xintDecSplitR{x}{N}` returns the second piece after the action of `\xintDecSplit`.

# 28 Commands of the **xintfrac** package

This package was first included in release 1.03 of the **xint** bundle. The general rule of the bundle that each macro first expands (what comes first, fully) each one of its arguments applies.

Frac f  $f$  stands for an integer or a fraction (see [section 8](#) for the accepted input formats) or something which expands to an integer or fraction. It is possible to use in the numerator or the denominator of  $f$  count registers and even expressions with infix arithmetic operators, under some rules which are explained in the previous [Use of count registers](#) section.

num x As in the **xint.sty** documentation,  $x$  stands for something which will internally be embedded in a `\numexpr`. It may thus be a count register or something like `4*\count 255 + 17`, etc..., but must expand to an integer obeying the TeX bound.

The fraction format on output is the scientific notation for the ‘float’ macros, and the  $A/B[n]$  format for all other fraction macros, with the exception of `\xintTrunc`, `\xintRound` (which produce decimal numbers) and `\xintIrr`, `\xintJrr`, `\xintRawWithZeros` (which returns an  $A/B$  with no trailing  $[n]$ , and prints the  $B$  even if it is 1), and `\xintPRaw` which does not print the  $[n]$  if  $n=0$  or the  $B$  if  $B=1$ .

To be certain to print an integer output without trailing  $[n]$  nor fraction slash, one should use either `\xintPRaw {\xintIrr {f}}` or `\xintNum {f}` when it is already known that  $f$  evaluates to a (big) integer. For example `\xintPRaw {\xintAdd {2/5}{3/5}}` gives a perhaps disappointing  $25/25^{53}$ , whereas `\xintPRaw {\xintIrr {\xintAdd {2/5}{3/5}}}` returns 1. As we knew the result was an integer we could have used `\xintNum {\xintAdd {2/5}{3/5}}=1`.

---

<sup>53</sup>yes, `\xintAdd` blindly multiplies denominators...

Some macros (such as `\xintiTrunc`, `\xintiRound`, and `\xintFac`) always produce directly integers on output.

## Contents

|     |                                          |    |     |                                                                                                                                       |    |

| .28 | <code>\xintFloatAdd</code>               | 84 |     |                                                                                                                                       |    |

### 28.1 `\xintNum`

*f* ★ The macro is extended to accept a fraction on input. But this fraction should reduce to an integer. If not an error will be raised. The original is available as `\xintiNum`. It is imprudent to apply `\xintNum` to numbers with a large power of ten given either in scientific notation or with the [n] notation, as the macro will add the necessary zeros to get an explicit integer.

### 28.2 `\xintifInt`

*Frac f nn* ★ `\xintifInt{f}{YES branch}{NO branch}` expandably chooses the YES branch if f reveals itself after expansion and simplification to be an integer. As with the other **xint** conditionals, both branches must be present although one of the two (or both, but why

then?) may well be an empty brace pair  $\{\}$ . As will all other **xint** conditionals, spaces in-between the braced things do not matter, but a space after the closing brace of the NO branch is significant.

### 28.3 \xintLen

$\text{Frac}_f$

- The original macro is extended to accept a fraction on input.

```
\xintLen {201710/298219}=11, \xintLen {1234/1}=4, \xintLen {1234}=4
```

### 28.4 \xintRaw

$\text{Frac}_f$

- This macro ‘prints’ the fraction  $f$  as it is received by the package after its parsing and expansion, in a form  $A/B[n]$  equivalent to the internal representation: the denominator  $B$  is always strictly positive and is printed even if it has value 1.

```
\xintRaw{\the\numexpr 571*987\relax.123e-10/\the\numexpr -201+59\relax e-7}=-563577123/142[-6]
```

### 28.5 \xintPRaw

$\text{Frac}_f$

- $\text{PRaw}$  stands for “pretty raw”. It does *not* show the  $[n]$  if  $n=0$  and does *not* show the  $B$  if  $B=1$ .

```
\xintPRaw {123e10/321e10}=123/321, \xintPRaw {123e9/321e10}=123/321[-1]  
          \xintPRaw {\xintIrr{861/123}}=7 vz. \xintIrr{861/123}=7/1
```

See also **\xintFrac** (or **\xintFwOver**) for math mode. As is exemplified above the **\xintIrr** macro which puts the fraction into irreducible form does not remove the  $/1$  if the fraction is an integer. One can use **\xintNum** for that, but there will be an error message if the fraction was not an integer; so the combination **\xintPRaw{\xintIrr{f}}** is the way to go.

### 28.6 \xintNumerator

$\text{Frac}_f$

- This returns the numerator corresponding to the internal representation of a fraction, with positive powers of ten converted into zeros of this numerator:

```
\xintNumerator {178000/25600000[17]}=17800000000000000000000000  
          \xintNumerator {312.289001/20198.27}=312289001  
          \xintNumerator {178000e-3/256e5}=178000  
          \xintNumerator {178.000/25600000}=178000
```

As shown by the examples, no simplification of the input is done. For a result uniquely associated to the value of the fraction first apply **\xintIrr**.

### 28.7 \xintDenominator

$\text{Frac}_f$

- This returns the denominator corresponding to the internal representation of the fraction:<sup>54</sup>

```
\xintDenominator {178000/25600000[17]}=25600000  
          \xintDenominator {312.289001/20198.27}=20198270000  
          \xintDenominator {178000e-3/256e5}=25600000000
```

---

<sup>54</sup>recall that the  $[]$  construct excludes presence of a decimal point.

```
\xintDenominator {178.000/25600000}=25600000000
```

As shown by the examples, no simplification of the input is done. The denominator looks wrong in the last example, but the numerator was tacitly multiplied by 1000 through the removal of the decimal point. For a result uniquely associated to the value of the fraction first apply `\xintIrr`.

## 28.8 `\xintRawWithZeros`

- `\frac{f}` ★ This macro ‘prints’ the fraction  $f$  (after its parsing and expansion) in A/B form, with A as returned by `\xintNumerator{f}` and B as returned by `\xintDenominator{f}`.

```
\xintRawWithZeros{\the\numexpr 571*987\relax.123e-10/\the\numexpr -201+59\relax e-7}=-563577123/142000000
```

## 28.9 `\xintREZ`

- `\frac{f}` ★ This command normalizes a fraction by removing the powers of ten from its numerator and denominator:

```
\xintREZ {178000/25600000[17]}=178/256[15]
\xintREZ {1780000000000e30/2560000000000e15}=178/256[15]
```

As shown by the example, it does not otherwise simplify the fraction.

## 28.10 `\xintFrac`

- `\frac{f}` ★ This is a L<sup>A</sup>T<sub>E</sub>X only command, to be used in math mode only. It will print a fraction, internally represented as something equivalent to A/B[n] as `\frac{A}{B}10^n`. The power of ten is omitted when  $n=0$ , the denominator is omitted when it has value one, the number being separated from the power of ten by a `\cdot`. `\xintFrac{178.000/25600000}` gives  $\frac{178000}{25600000}10^{-3}$ , `\xintFrac{178.000/1}` gives  $178000 \cdot 10^{-3}$ , `\xintFrac{3.5/5.7}` gives  $\frac{35}{57}$ , and `\xintFrac{\xintNum{\xintFac{10}}/\xintiSqr{\xintFac{5}}}}` gives 252. As shown by the examples, simplification of the input (apart from removing the decimal points and moving the minus sign to the numerator) is not done automatically and must be the result of macros such as `\xintIrr`, `\xintREZ`, or `\xintNum` (for fractions being in fact integers.)

## 28.11 `\xintSignedFrac`

- `\frac{f}` ★ This is as `\xintFrac` except that a negative fraction has the sign put in front, not in the numerator.

```
\[\xintFrac{-355/113}=\xintSignedFrac{-355/113}\]
```

$$\frac{-355}{113} = -\frac{355}{113}$$

## 28.12 `\xintFwOver`

- `\frac{f}` ★ This does the same as `\xintFrac` except that the `\over` primitive is used for the fraction (in case the denominator is not one; and a pair of braces contains the A`\over` B part). `\xintFwOver{178.000/25600000}` gives  $\frac{178000}{25600000}10^{-3}$ , `\xintFwOver{178.000/1}` gives

$178000 \cdot 10^{-3}$ ,  $\text{\xintFwOver}\{3.5/5.7\}$  gives  $\frac{35}{57}$ , and  $\text{\xintFwOver}\{\text{\xintNum}\{\text{\xintFac}\{10\}/\text{\xintiSqr}\{\text{\xintFac}\{5\}\}\}\}$  gives 252.

### 28.13 **\xintSignedFwOver**

- $f$  ★ This is as **\xintFwOver** except that a negative fraction has the sign put in front, not in the numerator.

```
\[\text{\xintFwOver}\{-355/113\}=\text{\xintSignedFwOver}\{-355/113\}\]
```

$$\frac{-355}{113} = -\frac{355}{113}$$

### 28.14 **\xintIrr**

- $f$  ★ This puts the fraction into its unique irreducible form:

```
\text{\xintIrr}\{178.256/256.178\}=6856/9853 = \frac{6856}{9853}
```

Note that the current implementation does not cleverly first factor powers of 2 and 5, so input such as  $\text{\xintIrr}\{2/3[100]\}$  will make **xintfrac** do the Euclidean division of  $2 \cdot 10^{100}$  by 3, which is a bit stupid.

Starting with release 1.08, **\xintIrr** does not remove the trailing /1 when the output is an integer. This was deemed better for various (stupid?) reasons and thus the output format is now *always* A/B with B>0. Use **\xintPRaw** on top of **\xintIrr** if it is needed to get rid of a possible trailing /1. For display in math mode, use rather **\xintFrac**{**\xintIrr** {f}} or **\xintFwOver**{**\xintIrr** {f}}.

### 28.15 **\xintJrr**

- $f$  ★ This also puts the fraction into its unique irreducible form:

```
\text{\xintJrr}\{178.256/256.178\}=6856/9853
```

This is faster than **\xintIrr** for fractions having some big common factor in the numerator and the denominator.

```
\text{\xintJrr}\{\text{\xintiPow}\{\text{\xintFac}\{15\}\}\{3\}/\text{\xintiiPrdExpr}\{\text{\xintFac}\{10\}\}\{\text{\xintFac}\{30\}\}\{\text{\xintFac}\{5\}\}\text{\relax}\}=1001/51705840
```

But to notice the difference one would need computations with much bigger numbers than in this example. Starting with release 1.08, **\xintJrr** does not remove the trailing /1 when the output is an integer.

### 28.16 **\xintTrunc**

- $x$   $f$  ★ **\xintTrunc**{x}{f} returns the start of the decimal expansion of the fraction f, with x digits after the decimal point. The argument x should be non-negative. When x=0, the integer part of f results, with an ending decimal point. Only when f evaluates to zero does **\xintTrunc** not print a decimal point. When f is not zero, the sign is maintained in the output, also when the digits are all zero.

```
\text{\xintTrunc}\{16\}\{-803.2028/20905.298\}=-0.0384210165289200  

\text{\xintTrunc}\{20\}\{-803.2028/20905.298\}=-0.03842101652892008523  

\text{\xintTrunc}\{10\}\{\text{\xintPow}\{-11\}\{-11\}\}=-0.0000000000  

\text{\xintTrunc}\{12\}\{\text{\xintPow}\{-11\}\{-11\}\}=-0.000000000003
```

```
\xintTrunc {12}{\xintAdd {-1/3}{3/9}}=0
```

The digits printed are exact up to and including the last one. The identity  $\xintTrunc{x}{-f} = -\xintTrunc{x}{f}$  holds.<sup>55</sup>

### 28.17 **\xintiTrunc**

- $x^{\text{num}} f^{\text{Frac}}$  ★  $\xintiTrunc{x}{f}$  returns the integer equal to  $10^x$  times what  $\xintTrunc{x}{f}$  would return.

```
\xintiTrunc {16}{-803.2028/20905.298}=-384210165289200
\xintiTrunc {10}{\xintPow {-11}{-11}}=0
\xintiTrunc {12}{\xintPow {-11}{-11}}=-3
```

Differences between  $\xintTrunc{0}{f}$  and  $\xintiTrunc{0}{f}$ : the former cannot be used inside integer-only macros, and the latter removes the decimal point, and never returns  $-0$  (and removes all superfluous leading zeros.)

### 28.18 **\xintRound**

- $x^{\text{num}} f^{\text{Frac}}$  ★  $\xintRound{x}{f}$  returns the start of the decimal expansion of the fraction  $f$ , rounded to  $x$  digits precision after the decimal point. The argument  $x$  should be non-negative. Only when  $f$  evaluates exactly to zero does  $\xintRound$  return  $0$  without decimal point. When  $f$  is not zero, its sign is given in the output, also when the digits printed are all zero.

```
\xintRound {16}{-803.2028/20905.298}=-0.0384210165289201
\xintRound {20}{-803.2028/20905.298}=-0.03842101652892008523
\xintRound {10}{\xintPow {-11}{-11}}=-0.0000000000
\xintRound {12}{\xintPow {-11}{-11}}=-0.000000000004
\xintRound {12}{\xintAdd {-1/3}{3/9}}=0
```

The identity  $\xintRound{x}{-f} = -\xintRound{x}{f}$  holds. And regarding  $(-11)^{-11}$  here is some more of its expansion:

```
-0.00000000000350493899481392497604003313162598556370...
```

### 28.19 **\xintiRound**

- $x^{\text{num}} f^{\text{Frac}}$  ★  $\xintiRound{x}{f}$  returns the integer equal to  $10^x$  times what  $\xintRound{x}{f}$  would return.

```
\xintiRound {16}{-803.2028/20905.298}=-384210165289201
\xintiRound {10}{\xintPow {-11}{-11}}=0
```

Differences between  $\xintRound{0}{f}$  and  $\xintiRound{0}{f}$ : the former cannot be used inside integer-only macros, and the latter removes the decimal point, and never returns  $-0$  (and removes all superfluous leading zeros.)

### 28.20 **\xintFloor**

- $f^{\text{Frac}}$  ★  $\xintFloor{f}$  returns the largest relative integer  $N$  with  $N \leq f$ .

```
\xintFloor {-2.13}=-3, \xintFloor {-2}=-2, \xintFloor {2.13}=2
```

---

<sup>55</sup>Recall that  $-\backslash macro$  is not valid as argument to any package macro, one must use  $\xintOpp{\backslash macro}$  or  $\xintiOpp{\backslash macro}$ , except inside  $\xinttheexpr\dots\relax$ .

### 28.21 \xintCeil

- $\text{Frac}_f$  ★  $\backslash\xintCeil\{f\}$  returns the smallest relative integer  $N$  with  $N > f$ .  
 $\backslash\xintCeil\{-2.13\}=-2, \backslash\xintCeil\{-2\}=-2, \backslash\xintCeil\{2.13\}=3$

### 28.22 \xintTFRAC

- $\text{Frac}_f$  ★  $\backslash\xintTFRAC\{f\}$  returns the fractional part,  $f=\text{trunc}(f)+\text{frac}(f)$ . The T stands for ‘Trunc’, and there could similar macros associated to ‘Round’, ‘Floor’, and ‘Ceil’. Inside  $\backslash\xintexpr..\backslash\text{relax}$ , the function `frac` is mapped to  $\backslash\xintTFRAC$ . Inside  $\backslash\xintfloatexpr..\backslash\text{relax}$ , `frac` first applies  $\backslash\xintTFRAC$  to its argument (which may be in float format, or an exact fraction), and only next makes the float conversion.

```
 $\backslash\xintTFRAC\{1235/97\}=71/97[0] \backslash\xintTFRAC\{-1235/97\}=-71/97[0]$ 
 $\backslash\xintTFRAC\{1235.973\}=973/1[-3] \backslash\xintTFRAC\{-1235.973\}=-973/1[-3]$ 
 $\backslash\xintTFRAC\{1.122435727e5\}=5727/1[-4]$ 
```

### 28.23 \xintE

- $\text{Frac}_{f^{\frac{\text{num}}{\text{den}}}}$  ★  $\backslash\xintE\{f\}\{x\}$  multiplies the fraction  $f$  by  $10^x$ . The *second* argument  $x$  must obey the TeX bounds. Example:

```
 $\backslash\text{count } 255 123456789 \backslash\xintE\{10\}\{\backslash\text{count } 255\}->10/1[123456789]$ 
```

Be careful that for obvious reasons such gigantic numbers should not be given to  $\backslash\xintNum$ , or added to something with a widely different order of magnitude, as the package always works to get the *exact* result. There is *no problem* using them for *float* operations:

```
 $\backslash\xintFloatAdd\{1e1234567890\}\{1\}=1.000000000000000e1234567890$ 
```

### 28.24 \xintFloatE

- $[^{\text{num}}_x] \text{Frac}_{f^{\frac{\text{num}}{\text{den}}}}$  ★  $\backslash\xintFloatE[P]\{f\}\{x\}$  multiplies the input  $f$  by  $10^x$ , and converts it to float format according to the optional first argument or current value of  $\backslash\xintDigits$ .

```
 $\backslash\xintFloatE\{1.23e37\}\{53\}=1.230000000000000e90$ 
```

### 28.25 \xintDigits, \xinttheDigits

The syntax  $\backslash\xintDigits := D$ ; (where spaces do not matter) assigns the value of  $D$  to the number of digits to be used by floating point operations. The default is 16. The maximal

- ★ value is 32767. The macro  $\backslash\xinttheDigits$  serves to print the current value.

### 28.26 \xintFloat

- $[^{\text{num}}_x] \text{Frac}_f$  ★ The macro  $\backslash\xintFloat[P]\{f\}$  has an optional argument  $P$  which replaces the current value of  $\backslash\xintDigits$ . The (rounded truncation of the) fraction  $f$  is then printed in scientific form, with  $P$  digits, a lowercase e and an exponent N. The first digit is from 1 to 9, it is preceded by an optional minus sign and is followed by a dot and  $P-1$  digits, the trailing zeros are not trimmed. In the exceptional case where the rounding went to the next power of ten, the output is  $10.0\dots0eN$  (with a sign, perhaps). The sole exception is for a zero value, which then gets output as  $0.e0$  (in an  $\backslash\xintCmp$  test it is the only possible output of  $\backslash\xintFloat$  or one of the ‘Float’ macros which will test positive for equality with zero).

```
\xintFloat[32]{1234567/7654321}=1.6129020457856418616360615134902e-1
\xintFloat[32]{1/\xintFac{100}}=1.0715102881254669231835467595192e-158
```

The argument to `\xintFloat` may be an `\xinttheexpr`-ession, like the other macros; only its final evaluation is submitted to `\xintFloat`: the inner evaluations of chained arguments are not at all done in ‘floating’ mode. For this one must use `\xintthefloatexpr`.

### 28.27 `\xintAdd`

$\frac{\text{Frac}}{f} \frac{\text{Frac}}{f}$

- ★ The original macro is extended to accept fractions on input. Its output will now always be in the form  $A/B[n]$ . The original is available as `\xintiAdd`.

### 28.28 `\xintFloatAdd`

$[\frac{\text{num}}{x}] \frac{\text{Frac}}{f} \frac{\text{Frac}}{f}$

- ★ `\xintFloatAdd [P]{f}{g}` first replaces  $f$  and  $g$  with their float approximations, with 2 safety digits. It then adds exactly and outputs in float format with precision  $P$  (which is optional) or `\xintDigits` if  $P$  was absent, the result of this computation.

### 28.29 `\xintSub`

$\frac{\text{Frac}}{f} \frac{\text{Frac}}{f}$

- ★ The original macro is extended to accept fractions on input. Its output will now always be in the form  $A/B[n]$ . The original is available as `\xintiSub`.

### 28.30 `\xintFloatSub`

$[\frac{\text{num}}{x}] \frac{\text{Frac}}{f} \frac{\text{Frac}}{f}$

- ★ `\xintFloatSub [P]{f}{g}` first replaces  $f$  and  $g$  with their float approximations, with 2 safety digits. It then subtracts exactly and outputs in float format with precision  $P$  (which is optional), or `\xintDigits` if  $P$  was absent, the result of this computation.

### 28.31 `\xintMul`

$\frac{\text{Frac}}{f} \frac{\text{Frac}}{f}$

- ★ The original macro is extended to accept fractions on input. Its output will now always be in the form  $A/B[n]$ . The original, only for big integers, and outputting a big integer, is available as `\xintiMul`.

### 28.32 `\xintFloatMul`

$[\frac{\text{num}}{x}] \frac{\text{Frac}}{f} \frac{\text{Frac}}{f}$

- ★ `\xintFloatMul [P]{f}{g}` first replaces  $f$  and  $g$  with their float approximations, with 2 safety digits. It then multiplies exactly and outputs in float format with precision  $P$  (which is optional), or `\xintDigits` if  $P$  was absent, the result of this computation.

### 28.33 `\xintSqr`

$\frac{\text{Frac}}{f}$

- ★ The original macro is extended to accept a fraction on input. Its output will now always be in the form  $A/B[n]$ . The original which outputs only big integers is available as `\xintiSqr`.

## 28.34 \xintDiv

- Frac**  $\frac{f}{f}$  ★ `\xintDiv{f}{g}` computes the fraction  $f/g$ . As with all other computation macros, no simplification is done on the output, which is in the form  $A/B[n]$ .

## 28.35 \xintFloatDiv

- $\left[ \frac{\text{num}}{x} \right] \frac{\text{Frac}}{f} \frac{\text{Frac}}{f} \star$  `\xintFloatDiv [P]{f}{g}` first replaces f and g with their float approximations, with 2 safety digits. It then divides exactly and outputs in float format with precision P (which is optional), or `\xintDigits` if P was absent, the result of this computation.

## 28.36 \xintFac

- Num<sub>f</sub>** ★ The original is extended to allow a fraction on input but this fraction  $f$  must simplify to a integer  $n$  (non negative and at most 999999, but already  $100000!$  is prohibitively time-costly). On output  $n!$  (no trailing  $/1[0]$ ). The original macro (which has less overhead) is still available as [\xintiFac](#).

## 28.37 \xintPow

- Frac Num** ★ `\xintPow{f}{g}`: the original macro is extended to accept fractions on input. The output will now always be in the form  $A/B[n]$  (even when the exponent vanishes: `\xintPow{2/3}{0}=1/1[0]`). The original is available as `\xintiPow`.

The exponent is allowed to be input as a fraction but it must simplify to an integer: `\xintPow {2/3}{10/2}=32/243[0]`. This integer will be checked to not exceed 999999999; future releases will presumably lower this limit as even much much smaller values already create gigantic numerators and denominators which can not be computed exactly in a reasonable time. Indeed  $2^{999999999}$  has 301029996 digits.

## 28.38 \xintFloatPow

- $\left[ \frac{\text{num}}{x} \right] f^{\frac{\text{num}}{x}}$  ★ `\xintFloatPow [P]{f}{x}` uses either the optional argument P or the value of `\xintDigits`. It computes a floating approximation to  $f^x$ .

The exponent  $x$  will be fed to a `\numexpr`, hence count registers are accepted on input for this  $x$ . And the absolute value  $|x|$  must obey the TeX bound. For larger exponents use the slightly slower routine `\xintFloatPower` which allows the exponent to be a fraction simplifying to an integer and does not limit its size. This slightly slower routine is the one to which  $^$  is mapped inside `\xintthefloatexpr... \relax`.

The macro `\xintFloatPow` chooses dynamically an appropriate number of digits for the intermediate computations, large enough to achieve the desired accuracy (hopefully).

```
\xintFloatPow [8]{3.1415}{1234567890}=1.6122066e613749456
```

## 28.39 \xintFloatPower

- $\text{xintFloatPower}[P][f][g]$  computes a floating point value  $f^g$  where the exponent  $g$  is not constrained to be at most the TeX bound 2147483647. It may even be a fraction A/B but must simplify to a (possibly big) integer.

```
\xintFloatPower [8]{1.00000000001}{1e12}=2.7182818e0
```

```
\xintFloatPower [8]{3.1415}{3e9}=1.4317729e1491411192
```

Note that  $3e9 > 2^{31}$ . But the number following e in the output must at any rate obey the TeX 2147483647 bound.

Inside an \xintfloatexpr-ession, \xintFloatPower is the function to which  $\wedge$  is mapped. The exponent may then be something like  $(144/3/(1.3-.5)-37)$  which is, in disguise, an integer.

The intermediate multiplications are done with a higher precision than \xintDigits or the optional P argument, in order for the final result to hopefully have the desired accuracy.

#### 28.40 \xintFloatSqrt

- $[^{\text{num}}_x] \overset{\text{Frac}}{f} \star$  \xintFloatSqrt[P]{f} computes a floating point approximation of  $\sqrt{f}$ , either using the optional precision P or the value of \xintDigits. The computation is done for a precision of at least 17 figures (and the output is rounded if the asked-for precision was smaller).

```
\xintFloatSqrt [50]{12.3456789e12}
≈ 3.5136418286444621616658231167580770371591427181243e6
\xintDigits:=50;\xintFloatSqrt {\xintFloatSqrt {2}}
≈ 1.1892071150027210667174999705604759152929720924638e0
```

#### 28.41 \xintSum

- $f \rightarrow * \overset{\text{Frac}}{f} \star$  The original command is extended to accept fractions on input and produce fractions on output. The output will now always be in the form A/B[n]. The original, for big integers only (in strict format), is available as \xintiiSum.

#### 28.42 \xintPrd

- $f \rightarrow * \overset{\text{Frac}}{f} \star$  The original is extended to accept fractions on input and produce fractions on output. The output will now always be in the form A/B[n]. The original, for big integers only (in strict format), is available as \xintiiPrd.

#### 28.43 \xintCmp

- $\overset{\text{Frac}}{f} \overset{\text{Frac}}{f} \star$  The macro is extended to fractions. Its output is still either -1, 0, or 1 with no forward slash nor trailing [n].

For choosing branches according to the result of comparing f and g, the following syntax is recommended: \xintSgnFork{\xintCmp{f}{g}}{code for f<g}{code for f=g}{code for f>g}.

#### 28.44 \xintIsOne

- $\overset{\text{Frac}}{f} \star$  See \xintIsOne (subsection 27.17).

#### 28.45 \xintGeq

- $\overset{\text{Frac}}{f} \overset{\text{Frac}}{f} \star$  The macro is extended to fractions. Beware that the comparison is on the *absolute values* of the fractions. Can be used as: \xintSgnFork{\xintGeq{f}{g}}{code for |f|<|g|}{code for |f|≥|g|}

28.46 \xintMax

Frac Frac  
 $f$   $f$

- The macro is extended to fractions. But now `\xintMax {2}{3}` returns  $3/1[0]$ . The original, for use with (possibly big) integers only, is available as `\xintiMax`: `\xintiMax {2}{3}=3`.

## 28.47 \xintMaxof

$$f \rightarrow *^{\text{Frac}} f$$

- See `\xintMaxof` (subsection 27.26).

## 28.48 \xintMin

Frac Frac  
 $f$   $f$

- The macro is extended to fractions. The original, for (big) integers only, is available as `\xintiMin`.

## 28.49 \xintMinof

$$f \rightarrow *^{\text{Frac}} f$$

- See `\xintMinof` (subsection 27.28).

## 28.50 \xintAbs

Frac  
*f*

- The macro is extended to fractions. The original, for (big) integers only, is available as `\xintiAbs`. Note that `\xintAbs {-2}=2/1[0]` whereas `\xintiAbs {-2}=-2`.

## 28.51 \xintSgn

Frac  
*f*

- The macro is extended to fractions. Naturally, its output is still either -1, 0, or 1 with no forward slash nor trailing [n].

## 28.52 \xint0pp

Frac  
*f*

- The macro is extended to fractions. The original is available as `\xintiOpp`. Note that `\xintOpp {3}` now outputs  $-3/1[0]$  whereas `\xintiOpp {3}` returns  $-3$ .

28.53 `\xintDivision`, `\xintQuo`, `\xintRem`, `\xintFDg`, `\xintLDg`,  
`\xintMON`, `\xintMMON`, `\xintOdd`

Frac  $f$  or  $\frac{f}{Frac}$

- These macros accept a fraction on input if this fraction in fact reduces to an integer (if not an `\xintError:NotAnInteger` will be raised). There is no difference in the format of the outputs, which are still (possibly big) integers without fraction slash nor trailing `[n]`, the sole difference is in the extended range of accepted inputs.

All have variants whose names start with `xintii` rather than `xint`; these variants accept on input only integers in the strict format (they do not use `\xintNum`). They thus have less overhead, and may be used when one is dealing exclusively with (big) integers. These variants are already available in `xint`, there is no need for `xintfrac` to be loaded.

\xintNum {1e80}

## 29 Expandable expressions with the `xintexpr` package

The `xintexpr` package was first released with version 1.07 of the `xint` bundle. It loads automatically `xintfrac`, hence also `xint` and `xinttools`.

The syntax is described in section 23 and section 24.

### 29.1 The `\xintexpr` expressions

- x ★* An `xintexpr`ression is a construct `\xintexpr<expandable_expression>\relax` where the expandable expression is read and completely expanded from left to right.

During this parsing, braced sub-content `{<expandable>}` may be serving as a macro parameter, or a branch of the ? two-way and : three-way operators; else it is treated in a special manner:

1. it is allowed to occur only at the spots where numbers are legal,
2. the `<expandable>` contents is then completely expanded as if it were put in a `\csname..\endcsname`<sup>56</sup> thus it escapes entirely the parser scope and infix notations will not be recognized except if the expanded macros know how to handle them by themselves,
3. and this complete expansion *must* produce a number or a fraction, possibly with decimal mark and trailing [n], the scientific notation is *not* authorized.

Braces are the only way to input some number or fraction with a trailing [n] as square brackets are *not* accepted in a `\xintexpr... \relax` if not within such braces.

An `\xintexpr..\relax` must end in a `\relax` (which will be absorbed). Like a `\numexpr` expression, it is not printable as is, nor can it be directly employed as argument to the other package macros. For this one must use one of the two equivalent forms:

- x ★* • `\xinttheexpr<expandable_expression>\relax`, or
- x ★* • `\xintthe\xintexpr<expandable_expression>\relax`.

---

<sup>56</sup>well, actually it *is* put in such a `\csname..\endcsname`.

The computations are done *exactly*, and with no simplification of the result. The output format for the result can be coded inside the expression through the use of one of the functions `round`, `trunc`, `float`, `reduce`.<sup>57</sup> Here are some examples

```
\xinttheexpr 1/5!-1/7!-1/9!\relax=1784764800/219469824000[0]
\xinttheexpr round(1/5!-1/7!-1/9!,18)\relax=0.008132164902998236
\xinttheexpr float(1/5!-1/7!-1/9!,18)\relax=813216490299823633[-20]
\xinttheexpr reduce(1/5!-1/7!-1/9!)\relax=2951/362880
\xinttheexpr 1.99^-2 - 2.01^-2 \relax=800/1599920001[4]
\xinttheexpr round(1.99^-2 - 2.01^-2, 10)\relax=0.0050002500
```

- the expression may contain arbitrarily many levels of nested parenthesized sub-expressions,
- sub-contents giving numbers of fractions should be either
  1. parenthesized,
  2. a sub-expression `\xintexpr... \relax`,
  3. or within braces.
- an expression can not be given as argument to the other package macros, nor printed, for this one must use `\xinttheexpr... \relax` or `\xintthe\xintexpr... \relax`,
- one does not use `\xinttheexpr... \relax` as a sub-constituent of an `\xintexpr... \relax` (or `\xinttheexpr... \relax`) but simply `\xintexpr... \relax`,
- each **xintexpr**ession is completely expandable and obtains its result in two expansion steps.

## 29.2 `\numexpr` or `\dimexpr` expressions, count and dimension registers and variables

New!

→ Count registers, count control sequences, dimen registers, dimen control sequences, skips and skip control sequences, `\numexpr`, `\dimexpr`, `\glueexpr` can be inserted directly, they will be unpacked using `\number` (which gives the internal value in terms of scaled points for the dimensional variables: 1 pt = 65536 sp; stretch and shrink components are thus discarded). Tacit multiplication is implied, when a number or decimal number prefixes such a register or control sequence.

$\text{\LaTeX}$  lengths are skip control sequences and  $\text{\LaTeX}$  counters should be inserted using `\value{}`.

In the case of numbered registers like `\count255` or `\dimen0`, the resulting digits will be re-parsed, so for example `\count255 0` is like `100` if `\the\count255` would give `10`. Control sequences define complete numbers, thus cannot be extended that way with more digits, on the other hand they are more efficient as they avoid the re-parsing of their unpacked contents.

A token list variable must be prefixed by `\the`, it will not be unpacked automatically (the parser will actually try `\number`, and thus fail). Do not use `\the` but only `\number` with a dimen or skip, as the `\xintexpr` parser doesn't understand pt and its presence is

---

<sup>57</sup>In `round` and `trunc` the second optional parameter is the number of digits of the fractional part; in `float` it is the total number of digits of the mantissa.

a syntax error. To use a dimension expressed in terms of points or other TeX recognized units, incorporate it in `\dimexpr... \relax`.

If one needs to optimize, `1.72\dimexpr 3.2pt\relax` is less efficient than `1.72*\{\number\dimexpr 3.2pt\relax\}/2.71828\relax` as the latter avoids re-parsing the digits of the representation of the dimension as scaled points.

```
\xinttheexpr 1.72\dimexpr 3.2pt\relax/2.71828\relax=
\xinttheexpr 1.72*\{\number\dimexpr 3.2pt\relax\}/2.71828\relax
36070980/271828[3]=36070980/271828[3]
```

Regarding how dimensional expressions are converted by TeX into scaled points see [Section 12](#).

## 29.3 Catcodes and spaces

### 29.3.1 `\xintexprSafeCatcodes`

Active characters will interfere with `\xintexpr`-essions. One may prefix them with `\string` within `\xintexpr... \relax`, thus preserving expandability, or there is the non-expandable `\xintexprSafeCatcodes` which can be issued before the use of `\xintexpr`. This command sets (not globally) the catcodes of the relevant characters to safe values. This is used internally by `\xintNewExpr` (restoring the catcodes on exit), hence `\xintNewExpr` does not have to be protected against active characters.

### 29.3.2 `\xintexprRestoreCatcodes`

Restores the catcodes to the earlier state.

Unbraced spaces inside an `\xinttheexpr... \relax` should mostly be innocuous (except inside macro arguments).

`\xintexpr` and `\xinttheexpr` are for the most part agnostic regarding catcodes: (unbraced) digits, binary operators, minus and plus signs as prefixes, dot as decimal mark, parentheses, may be indifferently of catcode letter or other or subscript or superscript, ..., it doesn't matter.<sup>58</sup>

The characters `+, -, *, /, ^, !, &, |, ?, :, <, >, =, (, )`, the dot and the comma should not be active as everything is expanded along the way. If one of them is active, it should be prefixed with `\string`.

Digits, slash, square brackets, minus sign, in the output from an `\xinttheexpr` are all of catcode 12. For `\xintthefloatexpr` the 'e' in the output is of catcode 11.

A macro with arguments will expand and grab its arguments before the parser may get a chance to see them, so the situation with catcodes and spaces is not the same within such macro arguments (or within braces used to protect square brackets).

## 29.4 Expandability

As is the case with all other package macros `\xintexpr` expands in two steps to its final (non-printable) result; and similarly for `\xinttheexpr`.

---

<sup>58</sup>Furthermore, although `\xintexpr` uses `\string`, it is (we hope) escape-char agnostic.

As explained above the expressions should contain only expandable material, except that braces are allowed when they enclose either a fraction (or decimal number) or something arbitrarily complicated but expanding (in a manner compatible to an expansion only context) to such a fraction or decimal number.

## 29.5 Memory considerations

The parser creates an undefined control sequence for each intermediate computation (this does not refer to the intermediate steps needed in the evaluations of the `\xintAdd`, `\xintMul`, etc... macros corresponding to the infix operators, but only to each conversion of such an infix operator into a computation). So, a moderately sized expression might create 10, or 20 such control sequences. On my  $\text{\TeX}$  installation, the memory available for such things is of circa 200,000 multi-letter control words. So this means that a document containing hundreds, perhaps even thousands of expressions will compile with no problem. But, if the package is used for computing plots<sup>59</sup>, this may cause a problem.

There is a solution.<sup>60</sup>

A document can possibly do tens of thousands of evaluations only if some formulas are being used repeatedly, for example inside loops, with counters being incremented, or with data being fetched from a file. So it is the same formula used again and again with varying numbers inside.

With the `\xintNewExpr` command, it is possible to convert once and for all an expression containing parameters into an expandable macro with parameters. Only this initial definition of this macro actually activates the `xintexpr` parser and will (very moderately) impact the hash-table: once this unique parsing is done, a macro with parameters is produced which is built-up recursively from the `\xintAdd`, `\xintMul`, etc... macros, exactly as it was necessary to do before the availability of the **xintexpr** package.

## 29.6 The `\xintNewExpr` command

The command is used as:

`\xintNewExpr{\myformula}[n]{<stuff>}`, where

- $\langle stuff \rangle$  will be inserted inside `\xinttheexpr . . . \relax`,
- $n$  is an integer between zero and nine, inclusive, and tells how many parameters will `\myformula` have (it is *mandatory* even if  $n=0$ <sup>61</sup>)
- the placeholders #1, #2, ..., # $n$  are used inside  $\langle stuff \rangle$  in their usual rôle.

The macro `\myformula` is defined without checking if it already exists,  $\text{\TeX}$  users might prefer to do first `\newcommand*{\myformula} {}` to get a reasonable error message in case `\myformula` already exists.

---

<sup>59</sup>this is not very probable as so far **xint** does not include a mathematical library with floating point calculations, but provides only the basic operations of algebra.

<sup>60</sup>which convinced me that I could stick with the parser implementation despite its potential impact on the hash-table.

<sup>61</sup>there is some use for `\xintNewExpr[0]` compared to an `\edef` as `\xintNewExpr` has some built-in catcode protection.

The definition of `\myformula` made by `\xintNewExpr` is global. The protection against active characters is done automatically.

It will be a completely expandable macro entirely built-up using `\xintAdd`, `\xintSub`, `\xintMul`, `\xintDiv`, `\xintPow`, etc... as corresponds to the expression written with the infix operators.

A “formula” created by `\xintNewExpr` is thus a macro whose parameters are given to a possibly very complicated combination of the various macros of **xint** and **xintfrac**; hence one can not use infix notation inside the arguments, as in for example `\myformula {28^7-35^12}` which would have been allowed by

```
\def\myformula #1{\xinttheexpr (#1)^3\relax}
```

One will have to do `\myformula {\xinttheexpr 28^7-35^12\relax}`, or redefine `\myformula` to have more parameters.

```
\xintNewExpr\DET[9]{ #1*#5*#9+#2*#6*#7+#3*#4*#8-#1*#6*#8-#2*#4*#9-#3*#5*#7 }
\meaning\DET:macro:#1#2#3#4#5#6#7#8#9->\romannumeral-'0\xintSub{\xint
Sub{\xintSub{\xintAdd{\xintAdd{\xintMul{\xintMul{#1}{#5}}{#9}}{\xintMul
{\xintMul{#2}{#6}}{#7}}}{\xintMul{\xintMul{#3}{#4}}{#8}}}{\xintMul{\xin
tMul{#1}{#6}}{#8}}}{\xintMul{\xintMul{#2}{#4}}{#9}}}{\xintMul{\xintMul{#3}{#5}}{#7}}
\xintNum{\DET {1}{1}{1}{10}{-10}{5}{11}{-9}{6}}=0
\xintNum{\DET {1}{2}{3}{10}{0}{-10}{21}{2}{-17}}=0
```

*Remark:* `\meaning` has been used within the argument to a `\printnumber` command, to avoid going into the right margin, but this zaps all spaces originally in the output from `\meaning`. Here is as an illustration the raw output of `\meaning` on the previous example:

```
macro:#1#2#3#4#5#6#7#8#9->\romannumeral -'0\xintSub {\xintSub {\xintSub
{\xintAdd {\xintAdd {\xintMul {\xintMul {#1}{#5}}{#9}}{\xintMul {\xintMul
{#2}{#6}}{#7}}}{\xintMul {\xintMul {#3}{#4}}{#8}}}{\xintMul {\xintMul {#1}{#6}}{#8}}}{\xin
Mul {\xintMul {#2}{#4}}{#9}}}{\xintMul {\xintMul {#3}{#5}}{#7}}
```

This is why `\printnumber` was used, to have breaks across lines.

### 29.6.1 Use of conditional operators

The 1.09a conditional operators `?` and `:` cannot be parsed by `\xintNewExpr` when they contain macro parameters `#1, ..., #9` within their scope. However replacing them with the functions `if` and, respectively `ifsgn`, the parsing should succeed. And the created macro will *not evaluate the branches to be skipped*, thus behaving exactly like `?` and `:` would have in the `\xintexpr`.

```
\xintNewExpr\Formula [3]
{ if((#1>#2) & (#2>#3), sqrt(#1-#2)*sqrt(#2-#3), #1^2+#3/#2) }
\meaning\Formula:macro:#1#2#3->\romannumeral-'0\xintifNotZero{\xintAND{
\xintGt{#1}{#2}}{\xintGt{#2}{#3}}}{\xintMul{\XINTinFloatSqrt[\XINTdigit
s]{\xintSub{#1}{#2}}}{\XINTinFloatSqrt[\XINTdigits]{\xintSub{#2}{#3}}}}
{\xintAdd{\xintPow{#1}{2}}{\xintDiv{#3}{#2}}}
```

This formula (with `\xintifNotZero`) will gobble the false branch.

Remark: this `\XINTinFloatSqrt` macro is a non-user package macro used internally within `\xintexpr`-essions, it produces the result in `A[n]` form rather than in scientific notation, and for reasons of the inner workings of `\xintexpr`-essions, this is necessary; a hand-made macro would have used instead the equivalent `\xintFloatSqrt`.

Another example

```
\xintNewExpr\myformula [3]
{ ifsgn(#1,#2/#3,#2-#3,#2*#3) }
macro:#1#2#3->\romannumeral -`0\xintifSgn{#1}{\xintDiv{#2}{#3}}{\xintSub
{#2}{#3}}{\xintMul{#2}{#3}}
```

Again, this macro gobbles the false branches, as would have the operator `:` inside an `\xintexpr`-ession.

### 29.6.2 Use of macros

For macros to be inserted within such a created `xint`-formula command, there are two cases:

- the macro does not involve the numbered parameters in its arguments: it may then be left as is, and will be evaluated once during the construction of the formula,
- it does involve at least one of the parameters as argument. Then:
  1. the whole thing (macro + argument) should be braced (not necessary if it is already included into a braced group),
  2. the macro should be coded with an underscore `_` in place of the backslash `\`,
  3. the parameters should be coded with a dollar sign `$1, $2`, etc...

Here is a silly example illustrating the general principle (the macros here have equivalent functional forms which are more convenient; but some of the more obscure package macros of `xint` dealing with integers do not have functions pre-defined to be in correspondance with them):

```
\xintNewExpr\myformI[2]{ {_xintRound{$1}{$2}} - {_xintTrunc{$1}{$2}} }
\meaning\myformI:
macro:#1#2->\romannumeral -`0\xintSub {\xintRound {#1}{#2}}{\xintTrunc {#1}{#2}}
\xintNewIIExpr\formula [3]{rem(#1,quo({_the_numexpr $2_relax},#3))}
\meaning\formula:
macro:#1#2#3->\romannumeral -`0\xintiiRem {#1}{\xintiiQuo {\the \numexpr
#2\relax }{#3}}
```

### 29.7 `xintiexpr`, `xinttheiexpr`

**x ★** Equivalent to doing `\xintexpr round(...)\relax`. Thus, only the final result is rounded to an integer. Half integers are rounded towards  $+\infty$  for positive numbers and towards  $-\infty$  for negative ones. Can be used on comma separated lists of expressions.

**1.09i warn→** Initially baptized `\xintnumexpr`, `\xintthenumexpr` but I am not too happy about this choice of name; one should keep in mind that `\numexpr`'s integer division rounds, whereas in `\xintiexpr`, the `/` is an exact fractional operation, and only the final result is rounded to an integer.

So `\xintnumexpr`, `\xintthenumexpr` are deprecated, and although still provided for the time being this might change in the future.

## 29.8 `\xintiexpr`, `\xinttheiexpr`

- x ★* This variant maps `/` to the euclidean quotient and deals almost only with (long) integers. It uses the ‘ii’ macros for addition, subtraction, multiplication, power, square, sums, products, euclidean quotient and remainder. The `round` and `trunc`, in the presence of the second optional argument, are mapped to `\xintiRound`, respectively `\xintiTrunc`, hence they always produce (long) integers.

To input a fraction to `round`, `trunc`, `floor` or `ceil` one can use braces, else the `/` will do the euclidean quotient. The minus sign should be put together with the fraction: `round({-30/78})` is illegal (even if the fraction had been an integer), use `round({-30/18})=-2`.

Decimal numbers are allowed only if postfix immediately with `e` or `E`, the number will then be truncated to an integer after multiplication by the power of ten with exponent the number following `e` or `E`.

```
\xinttheiexpr 13.4567e3+10000123e-3\relax=23456
```

A fraction within braces should be followed immediately by an `e` (or inside a `round`, `trunc`, etc...) to convert it into an integer as expected by the main operations. The truncation is only done after the `e` action.

The `reduce` function is not available and will raise un error. The `frac` function also. The `sqrt` function is mapped to `\xintiSqrt`.

Numbers in float notation, obtained via a macro like `\xintFloatSqrt`, are a bit of a challenge: they can not be within braces (this has been mentioned already, `e` is not legal within braces) and if not braced they will be truncated when the parser meets the `e`. The way out of the dilemma is to use a sub-expression:

```
\xinttheiexpr \xintFloatSqrt{2}\relax=1
\xinttheiexpr \xintexpr\xintFloatSqrt{2}\relax e10\relax=14142135623
\xinttheiexpr round(\xintexpr\xintFloatSqrt{2}\relax,10)\relax=14142135624
(recall that round is mapped within \xintiexpr..\relax to \xintiRound which always
outputs an integer).
```

The whole point of `\xintiexpr` is to gain some speed in integer only algorithms, and the above explanations related to how to use fractions therein are a bit peripheral. We observed of the order of 30% speed gain when dealing with numbers with circa one hundred digits, but this gain decreases the longer the manipulated numbers become and becomes negligible for numbers with thousand digits: the overhead from parsing fraction format is little compared to other expensive aspects of the expandable shuffling of tokens.

## 29.9 `\xintboolexpr`, `\xinttheboolexpr`

- x ★* Equivalent to doing `\xintexpr ... \relax` and returning 1 if the result does not vanish, and 0 is the result is zero. As `\xintexpr`, this can be used on comma separated lists of expressions, and will return a comma separated list of 0’s and 1’s.

## 29.10 `\xintfloatexpr`, `\xintthefloatexpr`

- x ★* `\xintfloatexpr... \relax` is exactly like `\xintexpr... \relax` but with the four binary

operations and the power function mapped to `\xintFloatAdd`, `\xintFloatSub`, `\xintFloatMul`, `\xintFloatDiv` and `\xintFloatPower`. The precision is from the current setting of `\xintDigits` (it can not be given as an optional parameter).

Currently, the factorial function hasn't yet a float version; so inside `\xintthefloatexpr . . . \relax`,  $n!$  will be computed exactly. Perhaps this will be improved in a future release.

Note that `1.000000001` and `(1+1e-9)` will not be equivalent for `D=\xinttheDigits` set to nine or less. Indeed the addition implicit in `1+1e-9` (and executed when the closing parenthesis is found) will provoke the rounding to 1. Whereas `1.000000001`, when found as operand of one of the four elementary operations is kept with `D+2` digits, and even more for the power function.

```
\xintDigits:= 9; \xintthefloatexpr (1+1e-9)-1\relax=0.e0
\xintDigits:= 9; \xintthefloatexpr 1.000000001-1\relax=1.00000000e-9
For the fun of it: \xintDigits:=20;
\xintthefloatexpr (1+1e-7)^1e7\relax=2.7182816925449662712e0
\xintDigits:=36;
\xintthefloatexpr ((1/13+1/121)*(1/179-1/173))/(1/19-1/18)\relax
      5.64487459334466559166166079096852897e-3
\xintFloat{\xinttheexpr ((1/13+1/121)*(1/179-1/173))/(1/19-1/18)\relax}
      5.64487459334466559166166079096852912e-3
```

The latter result is the rounding of the exact result. The previous one has rounding errors coming from the various roundings done for each sub-expression. It was a bit funny to discover that `maple`, configured with `Digits:=36`; and with decimal dots everywhere to let it input the numbers as floats, gives exactly the same result with the same rounding errors as does `\xintthefloatexpr`!

Using `\xintthefloatexpr` only pays off compared to using `\xinttheexpr` followed with `\xintFloat` if the computations turn out to involve hundreds of digits. For elementary calculations with hand written numbers (not using the scientific notation with exponents differing greatly) it will generally be more efficient to use `\xinttheexpr`. The situation is quickly otherwise if one starts using the Power function. Then, `\xintthefloat` is often useful; and sometimes indispensable to achieve the (approximate) computation in reasonable time.

We can try some crazy things:

```
\xintDigits:=12;\xintthefloatexpr 1.0000000000001^1e15\relax
      2.71828182846e0
```

Contrarily to some professional computing software which are our concurrents on this market, the `1.0000000000001` wasn't rounded to 1 despite the setting of `\xintDigits`; it would have been if we had input it as `(1+1e-15)`.

## 29.11 **\xintifboolexpr**

- xnn* ★ `\xintifboolexpr{<expr>}{{YES}}{{NO}}` does `\xinttheexpr <expr>\relax` and then executes the YES or the NO branch depending on whether the outcome was non-zero or zero. `<expr>` can involve various `&` and `|`, parentheses, `all`, `any`, `xor`, the `bool` or `togl` operators, but is not limited to them: the most general computation can be done, the test is on whether the outcome of the computation vanishes or not.

Will not work on an expression composed of comma separated sub-expressions.

## 29.12 `\xintifboolfloatexpr`

*xnn* ★ `\xintifboolfloatexpr{<expr>}{YES}{NO}` does `\xintthefloatexpr <expr>\relax` and then executes the YES or the NO branch depending on whether the outcome was non zero or zero.

## 29.13 `\xintifbooliexpr`

*xnn* ★ `\xintifbooliexpr{<expr>}{YES}{NO}` does `\xinttheiexpr <expr>\relax` and then executes the YES or the NO branch depending on whether the outcome was non zero or zero.

## 29.14 `\xintNewFloatExpr`

This is exactly like `\xintNewExpr` except that the created formulas are set-up to use `\xintthefloatexpr`. The precision used for numbers fetched as parameters will be the one locally given by `\xintDigits` at the time of use of the created formulas, not `\xintNewFloatExpr`. However, the numbers hard-wired in the original expression will have been evaluated with the then current setting for `\xintDigits`.

## 29.15 `\xintNewIExpr`

Like `\xintNewExpr` but using `\xinttheiexpr`. Former denomination was `\xintNewNumExpr` which is deprecated and should not be used.

## 29.16 `\xintNewBoolExpr`

Like `\xintNewExpr` but using `\xinttheboolexpr`.

## 29.17 Technicalities

As already mentioned `\xintNewExpr\myformula[n]` does not check the prior existence of a macro `\myformula`. And the number of parameters `n` given as mandatory argument withing square brackets should be (at least) equal to the number of parameters in the expression.

Obviously I should mention that `\xintNewExpr` itself can not be used in an expansion-only context, as it creates a macro.

- New! → The `\escapechar` setting may be arbitrary when using `\xintexpr`.  
The format of the output of `\xintexpr<stuff>\relax` is a ! (with catcode 11) followed by `\XINT_expr_use` which prints an error message in the document and in the log file if it is executed, then a token doing the actual printing and finally a token `\.=A/B[n]`. Using `\xinttheexpr` means zapping the first two things, the third one will then recover `A/B[n]` from the (presumably undefined, but it does not matter) control sequence `\.=A/B[n]`.

I decided to put all intermediate results (from each evaluation of an infix operators, or of a parenthesized subpart of the expression, or from application of the minus as prefix, or of the exclamation sign as postfix, or any encountered braced material) inside `\csname... \endcsname`, as this can be done expandably and encapsulates an arbitrarily long fraction in a single token (left with undefined meaning), thus providing tremendous relief to the programmer in his/her expansion control.

Syntax errors in the input such as using a one-argument function with two arguments will generate low-level TeX processing unrecoverable errors, with cryptic accompanying message.

Some other problems will give rise to ‘error messages’ macros giving some indication on the location and nature of the problem. Mainly, an attempt has been made to handle gracefully missing or extraneous parentheses.

When the scanner is looking for a number and finds something else not otherwise treated, it assumes it is the start of the function name and will expand forward in the hope of hitting an opening parenthesis; if none is found at least it should stop when encountering the `\relax` marking the end of the expressions.

Note that `\relax` is mandatory (contrarily to a `\numexpr`).

## 29.18 Acknowledgements

I was greatly helped in my preparatory thinking, prior to producing such an expandable parser, by the commented source of the `l3fp` package, specifically the `l3fp-parse.dtx` file. Also the source of the `calc` package was instructive, despite the fact that here for `\xintexpr` the principles are necessarily different due to the aim of achieving expandability.

# 30 Commands of the **xintbinhex** package

This package was first included in the 1.08 release of `xint`. It provides expandable conversions of arbitrarily long numbers to and from binary and hexadecimal.

The argument is first *f*-expanded. It then may start with an optional minus sign (unique, of category code other), followed with optional leading zeros (arbitrarily many, category code other) and then “digits” (hexadecimal letters may be of category code letter or other, and must be uppercased). The optional (unique) minus sign (plus sign is not allowed) is kept in the output. Leading zeros are allowed, and stripped. The hexadecimal letters on output are of category code letter, and uppercased.

## 31 Commands of the **xintgcd** package

This package was included in the original release 1.0 of the **xint** bundle.

Since release 1.09a the macros filter their inputs through the **\xintNum** macro, so one can use count registers, or fractions as long as they reduce to integers.

### 31.1 \xintGCD

- f Num f Num* ★ **\xintGCD{N}{M}** computes the greatest common divisor. It is positive, except when both N and M vanish, in which case the macro returns zero.

```
\xintGCD{10000}{1113}=1
\xintGCD{123456789012345}{9876543210321}=3
```

### 31.2 \xintGCDof

- f → \* f Num* ★ **\xintGCDof{{a}{b}{c}...}** computes the greatest common divisor of all integers a, b,

... The list argument may be a macro, it is  $f$ -expanded first and must contain at least one item.

### 31.3 **\xintLCM**

- $\begin{matrix} \text{Num} & \text{Num} \\ f & f \end{matrix} \star$   $\backslash\xintGCD\{N\}\{M\}$  computes the least common multiple. It is  $0$  if one of the two integers vanishes.

### 31.4 **\xintLCMof**

- $\begin{matrix} \text{Num} \\ f \rightarrow * \end{matrix} \begin{matrix} \text{Num} \\ f \end{matrix} \star$   $\backslash\xintLCMof\{\{a\}\{b\}\{c\}\dots\}$  computes the least common multiple of all integers  $a, b, \dots$ . The list argument may be a macro, it is  $f$ -expanded first and must contain at least one item.

### 31.5 **\xintBezout**

- $\begin{matrix} \text{Num} & \text{Num} \\ f & f \end{matrix} \star$   $\backslash\xintBezout\{N\}\{M\}$  returns five numbers  $A, B, U, V, D$  within braces.  $A$  is the first (expanded, as usual) input number,  $B$  the second,  $D$  is the GCD, and  $UA - VB = D$ .
- ```
\xintAssign {{\xintBezout {10000}{1113}}}\to\X
\meaning\X: macro:->{10000}{1113}{-131}{-1177}{1}.
\xintAssign {\xintBezout {10000}{1113}}\to\A\B\U\V\D
\A: 10000, \B: 1113, \U: -131, \V: -1177, \D: 1.
\xintAssign {\xintBezout {123456789012345}{9876543210321}}\to\A\B\U\V\D
\A: 123456789012345, \B: 9876543210321, \U: 256654313730, \V: 3208178892607,
\D: 3.
```

### 31.6 **\xintEuclideAlgorithm**

- $\begin{matrix} \text{Num} & \text{Num} \\ f & f \end{matrix} \star$   $\backslash\xintEuclideAlgorithm\{N\}\{M\}$  applies the Euclidean algorithm and keeps a copy of all quotients and remainders.

```
\xintAssign {{\xintEuclideAlgorithm {10000}{1113}}}\to\X
\meaning\X: macro:->{5}{10000}{1}{1113}{8}{1096}{1}{17}{64}{8}{2}
{1}{8}{0}.
```

The first token is the number of steps, the second is  $N$ , the third is the GCD, the fourth is  $M$  then the first quotient and remainder, the second quotient and remainder, ... until the final quotient and last (zero) remainder.

### 31.7 **\xintBezoutAlgorithm**

- $\begin{matrix} \text{Num} & \text{Num} \\ f & f \end{matrix} \star$   $\backslash\xintBezoutAlgorithm\{N\}\{M\}$  applies the Euclidean algorithm and keeps a copy of all quotients and remainders. Furthermore it computes the entries of the successive products of the 2 by 2 matrices  $\begin{pmatrix} q & 1 \\ 1 & 0 \end{pmatrix}$  formed from the quotients arising in the algorithm.

```
\xintAssign {{\xintEuclideAlgorithm {10000}{1113}}}\to\X
\meaning\X: macro:->{5}{10000}{0}{1}{1}{1113}{1}{0}{8}{1096}{8}{1}
{1}{17}{9}{1}{64}{8}{584}{65}{2}{1}{1177}{131}{8}{0}{10000}{1113}.
```

The first token is the number of steps, the second is  $N$ , then  $0, 1$ , the GCD,  $M, 1, 0$ , the first quotient, the first remainder, the top left entry of the first matrix, the bottom left entry, and then these four things at each step until the end.

### 31.8 \xintTypesetEuclideAlgorithm

**Num Num**  
*f f*

This macro is just an example of how to organize the data returned by `\xintEuclideAlgorithm`. Copy the source code to a new macro and modify it to what is needed.

```
\xintTypesetEuclideAlgorithm {123456789012345}{9876543210321}
123456789012345 = 12 × 9876543210321 + 4938270488493
9876543210321 = 2 × 4938270488493 + 2233335
4938270488493 = 2211164 × 2233335 + 536553
    2233335 = 4 × 536553 + 87123
    536553 = 6 × 87123 + 13815
    87123 = 6 × 13815 + 4233
    13815 = 3 × 4233 + 1116
    4233 = 3 × 1116 + 885
    1116 = 1 × 885 + 231
    885 = 3 × 231 + 192
    231 = 1 × 192 + 39
    192 = 4 × 39 + 36
    39 = 1 × 36 + 3
    36 = 12 × 3 + 0
```

### 31.9 \xintTypesetBezoutAlgorithm

**Num Num**  
*f f*

This macro is just an example of how to organize the data returned by `\xintBezoutAlgorithm`. Copy the source code to a new macro and modify it to what is needed.

```
\xintTypesetBezoutAlgorithm {10000}{1113}
10000 = 8 × 1113 + 1096
  8 = 8 × 1 + 0
  1 = 8 × 0 + 1
1113 = 1 × 1096 + 17
  9 = 1 × 8 + 1
  1 = 1 × 1 + 0
1096 = 64 × 17 + 8
  584 = 64 × 9 + 8
  65 = 64 × 1 + 1
  17 = 2 × 8 + 1
1177 = 2 × 584 + 9
  131 = 2 × 65 + 1
  8 = 8 × 1 + 0
10000 = 8 × 1177 + 584
  1113 = 8 × 131 + 65
  131 × 10000 − 1177 × 1113 = −1
```

## 32 Commands of the **xintseries** package

Some arguments to the package commands are macros which are expanded only later, when given their parameters. The arguments serving as indices are systematically given to

a `\numexpr` expressions (new with 1.06!) , hence  $f$ -expanded, they may be count registers, etc...

This package was first released with version 1.03 of the **xint** bundle.

We use  $\frac{\text{Frac}}{f}$  for the expansion type of various macro arguments, but if only **xint** and not **xintfrac** is loaded this should be more appropriately  $\frac{\text{Num}}{f}$ . The macro `\xintiSeries` is special and expects summing big integers obeying the strict format, even if **xintfrac** is loaded.

### 32.1 `\xintSeries`

$\frac{\text{num}}{x} \frac{\text{num}}{x} \frac{\text{Frac}}{f} \star$  `\xintSeries{A}{B}{\coeff}` computes  $\sum_{n=A}^{n=B} \coeff{n}$ . The initial and final indices must obey the `\numexpr` constraint of expanding to numbers at most  $2^{31}-1$ . The `\coeff` macro must be a one-parameter  $f$ -expandable command, taking on input an explicit number  $n$  and producing some number or fraction `\coeff{n}`; it is expanded at the time it is needed.<sup>62</sup>

```
\def\coeff {\#1{\xintiiMON{\#1}/#1.5} % (-1)^n/(n+1/2)
\edef\w {\xintSeries {0}{50}{\coeff}} % we want to re-use it
\edef\z {\xintJrr {\w}[0]} % the [0] for a microsecond gain.
% \xintJrr preferred to \xintIrr: a big common factor is suspected.
% But numbers much bigger would be needed to show the greater efficiency.
\[\sum_{n=0}^{n=50} \frac{(-1)^n}{n + \frac{1}{2}} = \xintFrac\z \]
```

$$\sum_{n=0}^{n=50} \frac{(-1)^n}{n + \frac{1}{2}} = \frac{173909338287370940432112792101626602278714}{110027467159390003025279917226039729050575}$$

For info, before action by `\xintJrr` the inner representation of the result has a denominator of `\xintLen {\xintDenominator\w}=117` digits. This troubled me as 101!! has only 81 digits: `\xintLen {\xintQuo {\xintFac {101}}{\xintiMul {\xintiPow {2}{50}}{\xintFac{50}}}}`=81. The explanation lies in the too clever to be efficient #1.5 trick. It leads to a silly extra  $5^{51}$  (which has 36 digits) in the denominator. See the explanations in the next section.

---

<sup>62</sup>`\xintiiMON` is like `\xintMON` but does not parse its argument through `\xintNum`, for efficiency; other macros of this type are `\xintiiAdd`, `\xintiiMul`, `\xintiiSum`, `\xintiiPrd`, `\xintiiMMON`, `\xintiiLDg`, `\xintiiFDg`, `\xintiiOdd`, ...

Note: as soon as the coefficients look like factorials, it is more efficient to use the **\xintRationalSeries** macro whose evaluation will avoid a denominator build-up; indeed the raw operations of addition and subtraction of fractions blindly multiply out denominators. So the raw evaluation of  $\sum_{n=0}^N 1/n!$  with **\xintSeries** will have a denominator equal to  $\prod_{n=0}^N n!$ . Needless to say this makes it more difficult to compute the exact value of this sum with  $N=50$ , for example, whereas with **\xintRationalSeries** the denominator does not get bigger than 50!.

For info: by the way  $\prod_{n=0}^{50} n!$  is easily computed by **xint** and is a number with 1394 digits. And  $\prod_{n=0}^{100} n!$  is also computable by **xint** (24 seconds on my laptop for the brute force iterated multiplication of all factorials, a specialized routine would do it faster) and has 6941 digits (this means more than two pages if printed...). Whereas  $100!$  only has 158 digits.

## 32.2 **\xintiSeries**

**num num** *x f* ★ **\xintiSeries**{A}{B}{\coeff} computes  $\sum_{n=A}^B \coeff{n}$  where **\coeff{n}** must *f*-expand to a (possibly long) integer in the strict format.

```
\def\coeff #1{\xintiTrunc {40}{\xintMON{#1}/#1.5}}%
% better:
\def\coeff #1{\xintiTrunc {40}
    {\the\numexpr 2*\xintiiMON{#1}\relax/\the\numexpr 2*#1+1\relax [0]}}%
% better still:
\def\coeff #1{\xintiTrunc {40}
    {\the\numexpr\ifodd #1 -2\else2\fi\relax/\the\numexpr 2*#1+1\relax [0]}}%
% (-1)^n/(n+1/2) times 10^40, truncated to an integer.
\[\sum_{n=0}^{n=50} \frac{(-1)^n}{n+\frac{1}{2}} \approx
    \xintTrunc {40}{\xintiSeries {0}{50}{\coeff}{-40}}\dots\]
```

The #1.5 trick to define the `\coeff` macro was neat, but  $1/3.5$ , for example, turns internally into  $10/35$  whereas it would be more efficient to have  $2/7$ . The second way of coding the wanted coefficient avoids a superfluous factor of five and leads to a faster evaluation. The third way is faster, after all there is no need to use `\xintMON` (or rather `\xintiMON` which has less parsing overhead) on integers obeying the T<sub>E</sub>X bound. The denominator having no sign, we have added the `[0]` as this speeds up (infinitesimally) the parsing.

$$\sum_{n=0}^{n=50} \frac{(-1)^n}{n + \frac{1}{2}} \approx 1.5805993064935250412367895069567264144810$$

We should have cut out at least the last two digits: truncating errors originating with the first coefficients of the sum will never go away, and each truncation introduces an uncertainty in the last digit, so as we have 40 terms, we should trash the last two digits, or at least round at 38 digits. It is interesting to compare with the computation where rounding rather than truncation is used, and with the decimal expansion of the exactly computed partial sum of the series:

```
\def\coeff #1{\xintiRound {40} % rounding at 40
  {\the\numexpr\ifodd #1 -2\else2\fi\relax/\the\numexpr 2*#1+1\relax [0]}% % (-1)^n/(n+1/2) times 10^40, rounded to an integer.
\[\sum_{n=0}^{n=50} \frac{(-1)^n}{n+\frac{1}{2}} \approx
  \xintTrunc {40}{\xintiSeries {0}{50}{\coeff}{-40}}\]
\def\exactcoeff #1%
  {\the\numexpr\ifodd #1 -2\else2\fi\relax/\the\numexpr 2*#1+1\relax [0]}%
\[\sum_{n=0}^{n=50} \frac{(-1)^n}{n+\frac{1}{2}}
 = \xintTrunc {50}{\xintSeries {0}{50}{\exactcoeff}}\dots\]
```

$$\sum_{n=0}^{n=50} \frac{(-1)^n}{n + \frac{1}{2}} \approx 1.5805993064935250412367895069567264144804$$

$$\sum_{n=0}^{n=50} \frac{(-1)^n}{n + \frac{1}{2}} = 1.58059930649352504123678950695672641448068680288367\dots$$

This shows indeed that our sum of truncated terms estimated wrongly the 39th and 40th digits of the exact result<sup>63</sup> and that the sum of rounded terms fared a bit better.

### 32.3 **\xintRationalSeries**

 `\xintRationalSeries{A}{B}{f}{ratio}` evaluates  $\sum_{n=A}^{n=B} F(n)$ , where  $F(n)$  is specified indirectly via the data of  $f=F(A)$  and the one-parameter macro `\ratio` which must be such that `\macro{n}` expands to  $F(n)/F(n-1)$ . The name indicates that `\xintRationalSeries` was designed to be useful in the cases where  $F(n)/F(n-1)$  is a rational function of  $n$  but it may be anything expanding to a fraction. The macro `\ratio` must be an expandable-only compatible command and expand to its value after iterated full expansion of its first token.  $A$  and  $B$  are fed to a `\numexpr` hence may be count registers or arithmetic expressions built

<sup>63</sup>as the series is alternating, we can roughly expect an error of  $\sqrt{40}$  and the last two digits are off by 4 units, which is not contradictory to our expectations.

with such; they must obey the TeX bound. The initial term  $f$  may be a macro  $\backslash f$ , it will be expanded to its value representing  $F(A)$ .

```

\def\ratio #1{2/#1[0]}% 2/n, to compute exp(2)
\cnta 0 % previously declared count
\loop \edef\z {\xintRationalSeries {0}{\cnta}{1}{\ratio }}%
\noindent$\sum_{n=0}^{\cnta}\frac{2^n}{n!}= \frac{\xintTrunc{12}}{\z}\dots = \frac{\xintFrac{\z=\xintFrac{\xintIrr{\z}}}\vtop to 5pt{}{\endgraf}}{1}

```

Such computations would become quickly completely inaccessible via the `\xintSeries` macros, as the factorials in the denominators would get all multiplied together: the raw addition and subtraction on fractions just blindly multiplies denominators! Whereas `\xintRationalSeries` evaluate the partial sums via a less silly iterative scheme.

$$\begin{aligned}
\sum_{n=0}^1 \frac{(-1)^n}{n!} &= 0 \cdots = 0 = 0 \\

\end{aligned}$$

We can incorporate an indeterminate if we define \ratio to be a macro with two parameters: \def\ratioexp #1#2{\xintDiv{#1}{#2}}% x/n: x=#1, n=#2. Then, if \x expands to some fraction x, the command

Observe that in this last example the `x` was directly inserted; if it had been a more complicated explicit fraction it would have been worthwhile to use `\ratioexp{x}` with `\x` defined to expand to its value. In the further situation where this fraction `x` is not explicit but

itself defined via a complicated, and time-costly, formula, it should be noted that `\xintRationalSeries` will do again the evaluation of `\x` for each term of the partial sum. The easiest is thus when `x` can be defined as an `\edef`. If however, you are in an expandable-only context and cannot store in a macro like `\x` the value to be used, a variant of `\xintRationalSeries` is needed which will first evaluate this `\x` and then use this result without recomputing it. This is `\xintRationalSeriesX`, documented next.

Here is a slightly more complicated evaluation:

```
\cnta 1
\loop \edef\z {\xintRationalSeries

    \xintTrunc{8}{\xintDiv{\z}{\w}\dots} \vtop to 5pt{}\endgraf
\ifnum\cnta<20 \advance\cnta 1 \repeat
```

$$\begin{aligned} \sum_{n=1}^1 \frac{1^n}{n!} / \sum_{n=0}^1 \frac{1^n}{n!} &= 0.50000000\dots \\ \sum_{n=2}^3 \frac{2^n}{n!} / \sum_{n=0}^3 \frac{2^n}{n!} &= 0.52631578\dots \\ \sum_{n=3}^5 \frac{3^n}{n!} / \sum_{n=0}^5 \frac{3^n}{n!} &= 0.53804347\dots \\ \sum_{n=4}^7 \frac{4^n}{n!} / \sum_{n=0}^7 \frac{4^n}{n!} &= 0.54317053\dots \\ \sum_{n=5}^9 \frac{5^n}{n!} / \sum_{n=0}^9 \frac{5^n}{n!} &= 0.54502576\dots \\ \sum_{n=6}^{11} \frac{6^n}{n!} / \sum_{n=0}^{11} \frac{6^n}{n!} &= 0.54518217\dots \\ \sum_{n=7}^{13} \frac{7^n}{n!} / \sum_{n=0}^{13} \frac{7^n}{n!} &= 0.54445274\dots \\ \sum_{n=8}^{15} \frac{8^n}{n!} / \sum_{n=0}^{15} \frac{8^n}{n!} &= 0.54327992\dots \\ \sum_{n=9}^{17} \frac{9^n}{n!} / \sum_{n=0}^{17} \frac{9^n}{n!} &= 0.54191055\dots \\ \sum_{n=10}^{19} \frac{10^n}{n!} / \sum_{n=0}^{19} \frac{10^n}{n!} &= 0.54048295\dots \end{aligned} \quad \begin{aligned} \sum_{n=11}^{21} \frac{11^n}{n!} / \sum_{n=0}^{21} \frac{11^n}{n!} &= 0.53907332\dots \\ \sum_{n=12}^{23} \frac{12^n}{n!} / \sum_{n=0}^{23} \frac{12^n}{n!} &= 0.53772178\dots \\ \sum_{n=13}^{25} \frac{13^n}{n!} / \sum_{n=0}^{25} \frac{13^n}{n!} &= 0.53644744\dots \\ \sum_{n=14}^{27} \frac{14^n}{n!} / \sum_{n=0}^{27} \frac{14^n}{n!} &= 0.53525726\dots \\ \sum_{n=15}^{29} \frac{15^n}{n!} / \sum_{n=0}^{29} \frac{15^n}{n!} &= 0.53415135\dots \\ \sum_{n=16}^{31} \frac{16^n}{n!} / \sum_{n=0}^{31} \frac{16^n}{n!} &= 0.53312615\dots \\ \sum_{n=17}^{33} \frac{17^n}{n!} / \sum_{n=0}^{33} \frac{17^n}{n!} &= 0.53217628\dots \\ \sum_{n=18}^{35} \frac{18^n}{n!} / \sum_{n=0}^{35} \frac{18^n}{n!} &= 0.53129566\dots \\ \sum_{n=19}^{37} \frac{19^n}{n!} / \sum_{n=0}^{37} \frac{19^n}{n!} &= 0.53047810\dots \\ \sum_{n=20}^{39} \frac{20^n}{n!} / \sum_{n=0}^{39} \frac{20^n}{n!} &= 0.52971771\dots \end{aligned}$$

### 32.4 `\xintRationalSeriesX`

`num num Frac Frac`  $x$   $x$   $f$   $f$   $\star$

`\xintRationalSeriesX{A}{B}{\first}{\ratio}{\g}` is a parametrized version of `\xintRationalSeries` where `\first` is now a one-parameter macro such that `\first{\g}` gives the initial term and `\ratio` is a two-parameter macro such that `\ratio{n}{\g}` represents the ratio of one term to the previous one. The parameter `\g` is evaluated only once at the beginning of the computation, and can thus itself be the yet unevaluated result of a previous computation.

Let `\ratio` be such a two-parameter macro; note the subtle differences between

```
\xintRationalSeries {A}{B}{\first}{\ratio}{\g}
\xintRationalSeriesX {A}{B}{\first}{\ratio}{\g}.
```

First the location of braces differ... then, in the former case `\first` is a *no-parameter* macro expanding to a fractional number, and in the latter, it is a *one-parameter* macro which will use `\g`. Furthermore the `X` variant will expand `\g` at the very beginning whereas the former non-`X` former variant will evaluate it each time it needs it (which is bad if this evaluation is time-costly, but good if `\g` is a big explicit fraction encapsulated in a macro).

The example will use the macro `\xintPowerSeries` which computes efficiently exact partial sums of power series, and is discussed in the next section.

```

\def\firstterm #1{1[0]}% first term of the exponential series
% although it is the constant 1, here it must be defined as a
% one-parameter macro. Next comes the ratio function for exp:
\def\ratioexp #1#2{\xintDiv {#1}{#2}}% x/n
% These are the  $(-1)^{n-1}/n$  of the  $\log(1+h)$  series:
\def\coefflog #1{\the\numexpr\ifodd #1 1\else-1\fi\relax/#1[0]}%
% Let L(h) be the first 10 terms of the  $\log(1+h)$  series and
% let E(t) be the first 10 terms of the  $\exp(t)$  series.
% The following computes  $E(L(a/10))$  for  $a=1,\dots,12$ .
% The following computes  $E(L(a/10))$  for  $a=1,\dots,12$ .
\cnta 0
\loop
\noindent\xintTrunc {18}{%
    \xintRationalSeriesX {0}{9}{\firstterm}{\ratioexp}
    {\xintPowerSeries{1}{10}{\coefflog}{\the\cnta[-1]}}}\dots
\endgraf
\ifnum\cnta < 12 \advance \cnta 1 \repeat

```

These completely exact operations rapidly create numbers with many digits. Let us print in full the raw fractions created by the operation illustrated above:

```
E(L(123[-3]))=44464159265194177715425414884885486619895497155261639
00742959135317921138508647797623508008144169817627741486630524932175
66759754097977420731516373336789722730765496139079185229545102248282
39119962102923779381174012211091973543316113275716895586401771088185
05853950798598438316179662071953915678034718321474363029365556301004
8000000000/3959408661224251932438755707826684577630388224000000000000
00000000 [-270] (length of numerator: 335)
```

We see that the denominators here remain the same, as our input only had various powers of ten as denominators, and `xintfrac` efficiently assemble (some only, as we can see) powers of ten. Notice that 1 more digit in an input denominator seems to mean 90 more in the raw output. We can check that with some other test cases:

```
E(L(1/7))=518138516117322604916074833164833344883840590133006168125

For info the last fraction put into irreducible form still has 288 digits in its denominator.<sup>64</sup> Thus decimal numbers such as  $0.123$  (equivalently  $123[-3]$ ) give less computing intensive tasks than fractions such as  $1/712$ : in the case of decimal numbers the (raw) denominators originate in the coefficients of the series themselves, powers of ten of the input within brackets being treated separately. And even then the numerators will grow with the size of the input in a sort of linear way, the coefficient being given by the order of series: here 10 from the log and 9 from the exp, so 90. One more digit in the input means 90 more digits in the numerator of the output: obviously we can not go on composing such partial sums of series and hope that **xint** will joyfully do all at the speed of light! Briefly said, imagine that the rules of the game make the programmer like a security guard at an airport scanning machine: a never-ending flux of passengers keep on arriving and all you can do is re-shuffle the first nine of them, organize marriages among some, execute some, move children farther back among the first nine only. If a passenger comes along with many hand luggages, this will slow down the process even if you move him to ninth position, because sooner or later you will have to digest him, and the children will be big too. There is no way to move some guy out of the file and to a discrete interrogatory room for separate treatment or to give him/her some badge saying ‘I left my stuff in storage box 357’.

Hence, truncating the output (or better, rounding) is the only way to go if one needs a general calculus of special functions. This is why the package **xintseries** provides, besides **\xintSeries**, **\xintRationalSeries**, or **\xintPowerSeries** which compute *exact*

---

<sup>64</sup>putting this fraction in irreducible form takes more time than is typical of the other computations in this document; so exceptionally I have hard-coded the 288 in the document source.

sums, also has `\xintFxPtPowerSeries` for fixed-point computations.

Update: release 1.08a of **xintseries** now includes a tentative naive `\xintFloatPowerSeries`.

### 32.5 `\xintPowerSeries`

`\xintPowerSeries{A}{B}{\coeff}{f}` evaluates the sum  $\sum_{n=A}^{n=B} \coeff{n} \cdot f^n$ . The initial and final indices are given to a `\numexpr` expression. The `\coeff` macro (which, as argument to `\xintPowerSeries` is expanded only at the time `\coeff{n}` is needed) should be defined as a one-parameter expandable command, its input will be an explicit number.

The `f` can be either a fraction directly input or a macro `\f` expanding to such a fraction. It is actually more efficient to encapsulate an explicit fraction `f` in such a macro, if it has big numerators and denominators ('big' means hundreds of digits) as it will then take less space in the processing until being (repeatedly) used.

This macro computes the *exact* result (one can use it also for polynomial evaluation). Starting with release 1.04 a Horner scheme for polynomial evaluation is used, which has the advantage to avoid a denominator build-up which was plaguing the 1.03 version.<sup>65</sup>

Note: as soon as the coefficients look like factorials, it is more efficient to use the `\xintRationalSeries` macro whose evaluation, also based on a similar Horner scheme, will avoid a denominator build-up originating in the coefficients themselves.

```
\def\geom #1{1[0]} % the geometric series
\def\f {5/17[0]}
\[\sum_{n=0}^{n=20} \left(\frac{5}{17}\right)^n = \frac{5757661159377657976885341}{4064231406647572522401601} = \frac{69091933912531895722624092}{48770776879770870268819212}

\def\coefflog #1{1/#1[0]}% 1/n
\def\f {1/2[0]}%
\[\log 2 \approx \sum_{n=1}^{n=20} \frac{1}{n \cdot 2^n} = \frac{42299423848079}{61025172848640}
\[\log 2 \approx \sum_{n=1}^{n=50} \frac{1}{n \cdot 2^n} = \frac{60463469751752265663579884559739219}{87230347965792839223946208178339840}

\cnta 1 % previously declared count
```

<sup>65</sup>with powers `f^k`, from `k=0` to `N`, a denominator `d` of `f` became `d^{1+2+...+N}`, which is bad. With the 1.04 method, the part of the denominator originating from `f` does not accumulate to more than `d^N`.

```
\loop % in this loop we recompute from scratch each partial sum!
% we can afford that, as \xintPowerSeries is fast enough.

### 32.6 **\xintPowerSeriesX**

$\frac{\text{num}}{x} \frac{\text{num}}{x} \frac{\text{Frac}}{f} \frac{\text{Frac}}{f}$

This is the same as **\xintPowerSeries** apart from the fact that the last parameter *f* is expanded once and for all before being then used repeatedly. If the *f* parameter is to be an explicit big fraction with many (dozens) digits, rather than using it directly it is slightly better to have some macro *\g* defined to expand to the explicit fraction and then use **\xintPowerSeries** with *\g*; but if *f* has not yet been evaluated and will be the output of a complicated expansion of some *\f*, and if, due to an expanding only context, doing **\edef \g{\f}** is no option, then **\xintPowerSeriesX** should be used with *\f* as last parameter.

```
\def\ratioexp #1#2{\xintDiv {#1}{#2}}% x/n

## 32.7 \xintFxPtPowerSeries

**\xintFxPtPowerSeries** {A} {B} {\coeff} {f} {D} computes  $\sum_{n=A}^{n=B} \coeff{n} \cdot f^n$  with each term of the series truncated to D digits after the decimal point. As usual, A and B are completely expanded through their inclusion in a **\numexpr** expression. Regarding D it will be similarly be expanded each time it is used inside an **\xintTrunc**. The one-parameter macro **\coeff** is similarly expanded at the time it is used inside the computations. Idem for f. If f itself is some complicated macro it is thus better to use the variant **\xintFxPtPowerSeriesX** which expands it first and then uses the result of that expansion.

The current (1.04) implementation is: the first power  $f^A$  is computed exactly, then truncated. Then each successive power is obtained from the previous one by multiplication by the exact value of  $f$ , and truncated. And  $\text{coeff}[n] \cdot f^n$  is obtained from that by multiplying by  $\text{coeff}[n]$  (untruncated) and then truncating. Finally the sum is computed exactly. Apart from that `\xintFxPtPowerSeries` (where FxPt means ‘fixed-point’) is like `\xintPowerSeries`.

There should be a variant for things of the type  $\sum c_n \frac{f^n}{n!}$  to avoid having to compute the factorial from scratch at each coefficient, the same way `\xintFxPtPowerSeries` does not compute  $f^n$  from scratch at each  $n$ . Perhaps in the next package release.

$$e^{-\frac{1}{2}} \approx$$

```
% One should **not** trust the final digits, as the potential truncation
% errors of up to 10^{-20} per term accumulate and never disappear! (the
% effect is attenuated by the alternating signs in the series). We can
% confirm that the last two digits (of our evaluation of the nineteenth
% partial sum) are wrong via the evaluation with more digits:
```

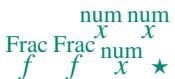

```
\xintFxPtPowerSeries {0}{19}{\coeffexp}{\f}{25}= 0.6065306597126334236037992
```

It is no difficulty for **xintfrac** to compute exactly, with the help of **\xintPowerSeries**, the nineteenth partial sum, and to then give (the start of) its exact decimal expansion:

$$\begin{aligned}\xintPowerSeries {0}{19}{\coeffexp}{\f} &= \frac{38682746160036397317757}{63777066403145711616000} \\ &= 0.606530659712633423603799152126\dots\end{aligned}$$

Thus, one should always estimate a priori how many ending digits are not reliable: if there are  $N$  terms and  $N$  has  $k$  digits, then digits up to but excluding the last  $k$  may usually be trusted. If we are optimistic and the series is alternating we may even replace  $N$  with  $\sqrt{N}$  to get the number  $k$  of digits possibly of dubious significance.

### 32.8 **\xintFxPtPowerSeriesX**

 ★ **\xintFxPtPowerSeriesX**{A}{B}{\coeff}{\f}{D} computes, exactly as **\xintFxPtPowerSeries**, the sum of  $\coeff{n} \cdot \f^n$  from  $n=A$  to  $n=B$  with each term of the series being *truncated* to D digits after the decimal point. The sole difference is that **\f** is first expanded and it is the result of this which is used in the computations.

Let us illustrate this on the numerical exploration of the identity

$$\log(1+x) = -\log(1/(1+x))$$

Let  $L(h)=\log(1+h)$ , and  $D(h)=L(h)+L(-h/(1+h))$ . Theoretically thus,  $D(h)=0$  but we shall evaluate  $L(h)$  and  $-h/(1+h)$  keeping only 10 terms of their respective series. We will assume  $|h|<0.5$ . With only ten terms kept in the power series we do not have quite 3 digits precision as  $2^{10}=1024$ . So it wouldn't make sense to evaluate things more precisely than, say circa 5 digits after the decimal points.

```

D(14/100): 2/1[-5]	D(42/100): 9/1[-5]
D(21/100): 3/1[-5]	D(49/100): 42/1[-5]

Let's say we evaluate functions on  $[-1/2, +1/2]$  with values more or less also in  $[-1/2, +1/2]$  and we want to keep 4 digits of precision. So, roughly we need at least 14 terms in series like the geometric or log series. Let's make this 15. Then it doesn't make sense to compute intermediate summands with more than 6 digits precision. So we compute with 6

digits precision but return only 4 digits (rounded) after the decimal point. This result with 4 post-decimal points precision is then used as input to the next evaluation.

```
\loop
\noindent \hbox to 2.5cm {\hss\texttt{D(\the\cnta/100): }}%
\xintRound{4}
{\xintAdd {\xintFxPtPowerSeriesX {1}{15}{\coefflog}{\the\cnta [-2]}{6}}

D(42/100): -0.0000
D(49/100): -0.0001
```

Not bad... I have cheated a bit: the ‘four-digits precise’ numeric evaluations were left unrounded in the final addition. However the inner rounding to four digits worked fine and made the next step faster than it would have been with longer inputs. The morale is that one should not use the raw results of `\xintFxPtPowerSeriesX` with the D digits with which it was computed, as the last are to be considered garbage. Rather, one should keep from the output only some smaller number of digits. This will make further computations faster and not less precise. I guess there should be some command to do this final truncating, or better, rounding, at a given number D'<D of digits. Maybe for the next release.

## 32.9 `\xintFloatPowerSeries`

[ $x^{\text{num}}$   $x^{\text{Frac}}$   $f^{\text{num}}$   $f^{\text{Frac}}$   $\star$ ]

`\xintFloatPowerSeries[P]{A}{B}{\coeff}{f}` computes  $\sum_{n=A}^{n=B} \coeff{n} \cdot f^n$  with a floating point precision given by the optional parameter P or by the current setting of `\xintDigits`.

In the current, preliminary, version, no attempt has been made to try to guarantee to the final result the precision P. Rather, P is used for all intermediate floating point evaluations. So rounding errors will make some of the last printed digits invalid. The operations done are first the evaluation of  $f^A$  using `\xintFloatPow`, then each successive power is obtained from this first one by multiplication by f using `\xintFloatMul`, then again with `\xintFloatMul` this is multiplied with `\coeff{n}`, and the sum is done adding one term at a time with `\xintFloatAdd`. To sum up, this is just the naive transformation of `\xintFxPtPowerSeries` from fixed point to floating point.

```
\def\coefflog #1{\the\numexpr\ifodd#1 1\else-1\fi\relax/#1[0]}%
\xintFloatPowerSeries [8]{1}{30}{\coefflog}{-1/2[0]}
-6.9314718e-1
```

## 32.10 `\xintFloatPowerSeriesX`

[ $x^{\text{num}}$   $x^{\text{Frac}}$   $f^{\text{num}}$   $f^{\text{Frac}}$   $\star$ ]

`\xintFloatPowerSeriesX[P]{A}{B}{\coeff}{f}` is like `\xintFloatPowerSeries` with the difference that f is expanded once and for all at the start of the computation, thus allowing efficient chaining of such series evaluations.

```
\def\coeffexp #1{1/\xintFac {#1}[0]}% 1/n! (exact, not float)
```

```
\def\coefflog #1{\the\numexpr\ifodd#1 1\else-1\fi\relax/#1[0]}%
\xintFloatPowerSeriesX [8]{0}{30}{\coeffexp}
{\xintFloatPowerSeries [8]{1}{30}{\coefflog}{-1/2[0]}}
5.0000001e-1
```

### 32.11 Computing $\log 2$ and $\pi$

In this final section, the use of `\xintFxPtPowerSeries` (and `\xintPowerSeries`) will be illustrated on the (expandable... why make things simple when it is so easy to make them difficult!) computations of the first digits of the decimal expansion of the familiar constants  $\log 2$  and  $\pi$ .

Let us start with  $\log 2$ . We will get it from this formula (which is left as an exercise):

$$\log(2) = -2 \log(1-13/256) - 5 \log(1-1/9)$$

The number of terms to be kept in the log series, for a desired precision of  $10^{-D}$  was roughly estimated without much theoretical analysis. Computing exactly the partial sums with `\xintPowerSeries` and then printing the truncated values, from  $D=0$  up to  $D=100$  showed that it worked in terms of quality of the approximation. Because of possible strings of zeros or nines in the exact decimal expansion (in the present case of  $\log 2$ , strings of zeros around the fortieth and the sixtieth decimals), this does not mean though that all digits printed were always exact. In the end one always ends up having to compute at some higher level of desired precision to validate the earlier result.

Then we tried with `\xintFxPtPowerSeries`: this is worthwhile only for  $D$ 's at least 50, as the exact evaluations are faster (with these short-length f's) for a lower number of digits. And as expected the degradation in the quality of approximation was in this range of the order of two or three digits. This meant roughly that the 3+1=4 ending digits were wrong. Again, we ended up having to compute with five more digits and compare with the earlier value to validate it. We use truncation rather than rounding because our goal is not to obtain the correct rounded decimal expansion but the correct exact truncated one.

```

0094933723...

```

Here is the code doing an exact evaluation of the partial sums. We have added a `+1` to the number of digits for estimating the number of terms to keep from the log series: we experimented that this gets exactly the first D digits, for all values from D=0 to D=100, except in one case (D=40) where the last digit is wrong. For values of D higher than 100 it is more efficient to use the code using `\xintFxPtPowerSeries`.

```

\def\LogTwo #1% get log(2)=-2log(1-13/256)- 5log(1-1/9)
{%
    \romannumeral0\expandafter\LogTwoDoIt \expandafter

        {\xintMul {5}{\xintPowerSeries {1}{#1}{\coefflog}{\xb}}}}%
}%
}%

```

Let us turn now to Pi, computed with the Machin formula. Again the numbers of terms to keep in the two `arctg` series were roughly estimated, and some experimentations showed that removing the last three digits was enough (at least for D=0–100 range). And the algorithm does print the correct digits when used with D=1000 (to be convinced of that one needs to run it for D=1000 and again, say for D=1010.) A theoretical analysis could help confirm that this algorithm always gets better than  $10^{-D}$  precision, but again, strings of zeros or nines encountered in the decimal expansion may falsify the ending digits, nines may be zeros (and the last non-nine one should be increased) and zeros may be nine (and the last non-zero one should be decreased).

```

% pi = 16 Arctg(1/5) - 4 Arctg(1/239) (John Machin's formula)
\def\coeffarctg #1{\the\numexpr\ifodd#1 -1\else1\fi\relax/%
                           \the\numexpr 2*#1+1\relax [0]}%
% the above computes  $(-1)^n/(2n+1)$ .
% Alternatives:

  {\xintMul {4/239}{\xintFxPtPowerSeries {0}{#2}{\coeffarctg}{\xb}{#3}}}}%
}%
\pi = \Machin {60}\dots
```

$$\pi = 3.141592653589793238462643383279502884197169399375105820974944\dots$$

Here is a variant \MachinBis, which evaluates the partial sums *exactly* using \xintPowerSeries, before their final truncation. No need for a “+3” then.

```
\def\MachinBis #1{%
  % #1 may be a count register,
  % the final result will be truncated to #1 digits post decimal point
  \romannumeral0\expandafter\MachinBisA \expandafter
  % number of terms for arctg(1/5):
  {\the\numexpr #1*5/7\expandafter}\expandafter
  % number of terms for arctg(1/239):
  {\the\numexpr #1*10/45\expandafter}\expandafter
  % allow #1 to be a count register:
  {\the\numexpr #1\relax }%
}
\def\MachinBisA #1#2#3%
{\xinttrunc {#3} %
{\xintSub
  {\xintMul {16/5}{\xintPowerSeries {0}{#1}{\coeffarctg}{\xa}}}
  {\xintMul {4/239}{\xintPowerSeries {0}{#2}{\coeffarctg}{\xb}}}}%
}
```

Let us use this variant for a loop showing the build-up of digits:

```
\cnta 0 % previously declared \count register
\loop
  \MachinBis{\cnta} \endgraf % Plain's \loop does not accept \par
  \ifnum\cnta < 30 \advance\cnta 1 \repeat
```

\immediate\write\outfile {\Machin {1000}}
\immediate\closeout\outfile
```

This will create a file with the correct first 1000 digits of  $\pi$  after the decimal point. On my laptop (a 2012 model) this took about 42 seconds last time I tried (and for 200 digits it is less than 1 second). As mentioned in the introduction, the file **pi.tex** by D. ROEGEL shows that orders of magnitude faster computations are possible within  $\text{\TeX}$ , but recall our constraints of complete expandability and be merciful, please.

**Why truncating rather than rounding?** One of our main competitors on the market of scientific computing, a canadian product (not encumbered with expandability constraints, and having barely ever heard of  $\text{\TeX}$  ;), prints numbers rounded in the last digit. Why didn't we follow suit in the macros **\xintFxPtPowerSeries** and **\xintFxPtPowerSeriesX**? To round at  $D$  digits, and excluding a rewrite or cloning of the division algorithm which anyhow would add to it some overhead in its final steps, **xintfrac** needs to truncate at  $D+1$ , then round. And rounding loses information! So, with more time spent, we obtain a worst result than the one truncated at  $D+1$  (one could imagine that additions and so on, done with only  $D$  digits, cost less; true, but this is a negligible effect per summand compared to the additional cost for this term of having been truncated at  $D+1$  then rounded). Rounding is the way to go when setting up algorithms to evaluate functions destined to be composed one after the other: exact algebraic operations with many summands and an **f** variable which is a fraction are costly and create an even bigger fraction; replacing **f** with a reasonable rounding, and rounding the result, is necessary to allow arbitrary chaining.

But, for the computation of a single constant, we are really interested in the exact decimal expansion, so we truncate and compute more terms until the earlier result gets validated. Finally if we do want the rounding we can always do it on a value computed with  $D+1$  truncation.

## 33 Commands of the **xintcfrac** package

This package was first included in release 1.04 of the **xint** bundle.

### 33.1 Package overview

A *simple* continued fraction has coefficients  $[c_0, c_1, \dots, c_N]$  (usually called partial quotients, but I really dislike this entrenched terminology), where  $c_0$  is a positive or negative integer and the others are positive integers. As we will see it is possible with **xintcfrac** to specify the coefficient function  $c : n \rightarrow cn$ . Note that the index then starts at zero as indicated. With the **amsmath** macro `\cfrac` one can display such a continued fraction as

$$c_0 + \cfrac{1}{c_1 + \cfrac{1}{c_2 + \cfrac{1}{c_3 + \cfrac{1}{\ddots}}}}$$

Here is a concrete example:

$$\frac{208341}{66317} = 3 + \cfrac{1}{7 + \cfrac{1}{15 + \cfrac{1}{1 + \cfrac{1}{292 + \frac{1}{2}}}}}$$

But the difference with **amsmath**'s `\cfrac` is that this was input as

```
\[ \xintFrac {208341/66317}=\xintCFrac {208341/66317} \]
```

The command `\xintCFrac` produces in two expansion steps the whole thing with the many

chained \cfrac's and all necessary braces, ready to be printed, in math mode. This is L<sup>A</sup>T<sub>E</sub>X only and with the amsmath package (we shall mention another method for Plain T<sub>E</sub>X users of amstex).

A *generalized* continued fraction has the same structure but the numerators are not restricted to be ones, and numbers used in the continued fraction may be arbitrary, also fractions, irrationals, indeterminates. The *centered* continued fraction associated to a rational number is an example:

$$\frac{915286}{188421} = 5 - \cfrac{1}{7 + \cfrac{1}{39 - \cfrac{1}{53 - \cfrac{1}{13}}}} = 4 + \cfrac{1}{1 + \cfrac{1}{6 + \cfrac{1}{38 + \cfrac{1}{1 + \cfrac{1}{51 + \cfrac{1}{1 + \cfrac{1}{12}}}}}}}$$

\[ \xintFrac {915286/188421}=\xintGCFrac {\xintFtoCC {915286/188421}} \] The command \xintGCFrac, contrarily to \xintCfrac, does not compute anything, it just typesets. Here, it is the command \xintFtoCC which did the computation of the centered continued fraction of f. Its output has the ‘inline format’ described in the next paragraph. In the display, we also used \xintCfrac (code not shown), for comparison of the two types of continued fractions.

A generalized continued fraction may be input ‘inline’ as:

$a_0+b_0/a_1+b_1/a_2+b_2/\dots/a_{(n-1)}+b_{(n-1)}/a_n$

Fractions among the coefficients are allowed but they must be enclosed within braces. Signed integers may be left without braces (but the + signs are mandatory). Or, they may be macros expanding (in two steps) to some number or fractional number.

\xintGCFrac {1+-1/57+\xintPow {-3}{7}/\xintQuo {132}{25}}

$$\frac{1907}{1902} = 1 - \cfrac{1}{57 - \cfrac{2187}{5}}$$

The left hand side was obtained with the following code:

\xintFrac{\xintGtoF {1+-1/57+\xintPow {-3}{7}/\xintQuo {132}{25}}} It uses the macro \xintGtoF to convert a generalized fraction from the ‘inline format’ to the fraction it evaluates to.

A simple continued fraction is a special case of a generalized continued fraction and may be input as such to macros expecting the ‘inline format’, for example -7+1/6+1/19+1/1+1/33. There is a simpler comma separated format:

```
\xintFrac{\xintCstoF{-7,6,19,1,33}}=\xintCFrac{\xintCstoF{-7,6,19,1,33}}
```

$$\frac{-28077}{4108} = -7 + \cfrac{1}{6 + \cfrac{1}{19 + \cfrac{1}{1 + \cfrac{1}{33}}}}$$

This comma separated format may also be used with fractions among the coefficients: in that case, computing with `\xintFtoCs` from the resulting `f` its real coefficients will give a new comma separated list with only integers. This list has no spaces: the spaces in the display below arise from the math mode processing.

```
\xintFrac{1084483/398959}=[\xintFtoCs{1084483/398959}]
```

$$\frac{1084483}{398959} = [2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 1, 1, 10, 2]$$

If one prefers other separators, one can use `\xintFtoCx` whose first argument will be the separator to be used.

```
\xintFrac{2721/1001}=\xintFtoCx {+1/}{2721/1001})\cdots)
```

$$\frac{2721}{1001} = 2 + 1/(1 + 1/(2 + 1/(1 + 1/(1 + 1/(4 + 1/(1 + 1/(1 + 1/(6 + 1/(2) \cdots)))$$

People using Plain T<sub>E</sub>X and `amstex` can achieve the same effect as `\xintCFrac` with: \$\$\xintFwOver{2721/1001}=\xintFtoCx {+\cfrac{1}{}}{2721/1001}\endcfrac\$\$

Using `\xintFtoCx` with first argument an empty pair of braces {} will return the list of the coefficients of the continued fraction of `f`, without separator, and each one enclosed in a pair of group braces. This can then be manipulated by the non-expandable macro `\xintAssignArray` or the expandable ones `\xintApply` and `\xintListWithSep`.

As a shortcut to using `\xintFtoCx` with separator `1+/-`, there is `\xintFtoGC`:

```
2721/1001=\xintFtoGC {2721/1001}
2721/1001=2+1/1+1/2+1/1+1/1+1/4+1/1+1/1+1/6+1/2
```

Let us compare in that case with the output of `\xintFtoCC`:

```
2721/1001=\xintFtoCC {2721/1001}
2721/1001=3+-1/4+-1/2+1/5+-1/2+1/7+-1/2
```

The ‘`\printnumber`’ macro which we use to print long numbers can also be useful on long continued fractions.

```
\printnumber{\xintFtoCC {35037018906350720204351049/%
244241737886197404558180}}
143+1/2+1/5+-1/4+-1/4+-1/4+-1/3+1/2+1/2+1/6+-1/22+1/2+1/10+-1/5+-
1/11+-1/3+1/4+-1/2+1/2+1/4+-1/2+1/23+1/3+1/8+-1/6+-1/9. If we apply
\xintGtoF to this generalized continued fraction, we discover that the original fraction
was reducible:
```

```
\xintGtoF {143+1/2+...+-1/9}=2897319801297630107/20197107104701740
```

When a generalized continued fraction is built with integers, and numerators are only 1’s or -1’s, the produced fraction is irreducible. And if we compute it again with the last sub-fraction omitted we get another irreducible fraction related to the bigger one by a Bezout identity. Doing this here we get:

```
\xintGtoF {143+1/2+...+-1/6}=328124887710626729/2287346221788023
```

and indeed:

$$\left| \begin{array}{cc} 2897319801297630107 & 328124887710626729 \\ 20197107104701740 & 2287346221788023 \end{array} \right| = 1$$

More generally the various fractions obtained from the truncation of a continued fraction to its initial terms are called the convergents. The commands of **xintcfrac** such as **\xintFtoCv**, **\xintFtoCCv**, and others which compute such convergents, return them as a list of braced items, with no separator. This list can then be treated either with **\xintAssignArray**, or **\xintListWithSep**, or any other way (but then, some TeX programming knowledge will be necessary). Here is an example:

```
$$\xintFrac{915286/188421}\to \xintListWithSep {,%}
{\xintApply{\xintFrac}{\xintFtoCv{915286/188421}}}}$$

$$\frac{915286}{188421} \rightarrow 4, 5, \frac{34}{7}, \frac{1297}{267}, \frac{1331}{274}, \frac{69178}{14241}, \frac{70509}{14515}, \frac{915286}{188421}$$

$$\$ \$ \xintFrac{915286/188421}\to \xintListWithSep {,%}
{\xintApply{\xintFrac}{\xintFtoCCv{915286/188421}}}}\$ \$$$

$$\frac{915286}{188421} \rightarrow 5, \frac{34}{7}, \frac{1331}{274}, \frac{70509}{14515}, \frac{915286}{188421}$$

```

We thus see that the ‘centered convergents’ obtained with **\xintFtoCCv** are among the fuller list of convergents as returned by **\xintFtoCv**.

Here is a more complicated use of **\xintApply** and **\xintListWithSep**. We first define a macro which will be applied to each convergent:

```
\newcommand{\mymacro}[1]{\$ \$ \xintFrac{#1}=[\xintFtoCs{#1}]\$ \$ \vtop{ to 6pt{}}}
```

Next, we use the following code:

```
\$ \$ \xintFrac{49171/18089}\to {}\$ \$ \xintListWithSep {, }{\xintApply{\mymacro}{\xintFtoCv{49171/18089}}}
```

It produces:

$\frac{49171}{18089} \rightarrow 2 = [2], 3 = [3], \frac{8}{3} = [2, 1, 2], \frac{11}{4} = [2, 1, 3], \frac{19}{7} = [2, 1, 2, 2], \frac{87}{32} = [2, 1, 2, 1, 1, 4],$   
 $\frac{106}{39} = [2, 1, 2, 1, 1, 5], \frac{193}{71} = [2, 1, 2, 1, 1, 4, 2], \frac{1264}{465} = [2, 1, 2, 1, 1, 4, 1, 1, 6], \frac{1457}{536} =$   
 $[2, 1, 2, 1, 1, 4, 1, 1, 7], \frac{2721}{1001} = [2, 1, 2, 1, 1, 4, 1, 1, 6, 2], \frac{23225}{8544} = [2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8],$   
 $\frac{49171}{18089} = [2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8, 2].$

The macro **\xintCnF** allows to specify the coefficients as functions of the index. The values to which expand the coefficient function do not have to be integers.

```
\def\cn #1{\xintiPow {2}{#1}}% 2^n
\[\xintFrac{\xintCnF {6}{\cn}}=\xintCfrac [1]{\xintCnF {6}{\cn}}\]

$$\frac{3541373}{2449193} = 1 + \cfrac{1}{2 + \cfrac{1}{4 + \cfrac{1}{8 + \cfrac{1}{16 + \cfrac{1}{32 + \cfrac{1}{64}}}}}}$$

```

Notice the use of the optional argument [l] to `\xintCFrac`. Other possibilities are [r] and (default) [c].

$$\begin{aligned} & \text{\def\cn{\#1{\xintPow{2}{-\#1}}\% 1/2^n}} \\ & \text{\def\an{\#1{\the\numexpr 2*\#1+1\relax}\%} \\ & \text{\def\bn{\#1{\the\numexpr (\#1+1)*(\#1+1)\relax}\%} \\ & [\ \xintFrac{\xintCtoF{6}{\cn}} = \xintGCFrac[r]{\xintCtoGC{6}{\cn}} \\ & = [\xintFtoCs{\xintCtoF{6}{\cn}}]\ ]} \\ \frac{3159019}{2465449} &= 1 + \cfrac{1}{1 + \cfrac{1}{\frac{1}{2} + \cfrac{1}{1 + \cfrac{1}{\frac{1}{4} + \cfrac{1}{1 + \cfrac{1}{\frac{1}{8} + \cfrac{1}{1 + \cfrac{1}{\frac{1}{16} + \cfrac{1}{1 + \cfrac{1}{\frac{1}{32} + \cfrac{1}{1 + \cfrac{1}{64}}}}}}}}}}}} = [1, 3, 1, 1, 4, 14, 1, 1, 1, 1, 79, 2, 1, 1, 2] \end{aligned}$$

We used `\xintCtoGC` as we wanted to display also the continued fraction and not only the fraction returned by `\xintCtoF`.

There are also `\xintGCntoF` and `\xintGCntoGC` which allow the same for generalized fractions. The following initial portion of a generalized continued fraction for  $\pi$ :

$$\begin{aligned} \frac{92736}{29520} &= \cfrac{4}{1 + \cfrac{1}{4 + \cfrac{9}{3 + \cfrac{16}{5 + \cfrac{25}{7 + \cfrac{11}{9}}}}} = 3.1414634146\dots \end{aligned}$$

was obtained with this code:

```
\def\an{\#1{\the\numexpr 2*\#1+1\relax}\%}
\def\bn{\#1{\the\numexpr (\#1+1)*(\#1+1)\relax}\%}
[ \xintFrac{\xintDiv{4}{\xintGCntoF{5}{\an}}{\bn}} =
  \cfrac{4}{\xintGCFrac{\xintGCntoGC{5}{\an}}{\bn}} =
\xintTrunc{10}{\xintDiv{4}{\xintGCntoF{5}{\an}}{\bn}}\dots]
```

We see that the quality of approximation is not fantastic compared to the simple continued fraction of  $\pi$  with about as many terms:

```
[ \xintFrac{\xintCstoF{3,7,15,1,292,1,1}}=
  \xintGCFrac{3+1/7+1/15+1/1+1/292+1/1+1/1}=
\xintTrunc{10}{\xintCstoF{3,7,15,1,292,1,1}}\dots]
```

$$\begin{aligned} \frac{208341}{66317} &= 3 + \cfrac{1}{7 + \cfrac{1}{15 + \cfrac{1}{1 + \cfrac{1}{292 + \cfrac{1}{1 + \cfrac{1}{1}}}}} = 3.1415926534\dots \end{aligned}$$

To conclude this overview of most of the package functionalities, let us explore the convergents of Euler's number  $e$ .

```

\def\cn {\the\numexpr\ifcase \numexpr #1+3-3*((#1+2)/3)\relax
           1\or1\or2*(#1/3)\fi\relax }

% produces the pattern 1,1,2,1,1,4,1,1,6,1,1,8,... which are the
% coefficients of the simple continued fraction of e-1.

\cnta 0
\def\mymacro #1{\advance\cnta by 1
    \noindent
    \hbox to 3em {\hfil\small\textrm{\tiny\the\cnta.}}%
    \$\xintTrunc {30}{\xintAdd {1[0]}{#1}}\dots=
    \xintFrac{\xintAdd {1[0]}{#1}}\$%
\xintListWithSep{\vtop to 6pt{}\vbox to 12pt{}\par}
    {\xintApply\mymacro{\xintIcstoCv{\xintCnToCs {35}\{\cn\}}}}

```

The volume of computation is kept minimal by the following steps:

- a comma separated list of the first 36 coefficients is produced by `\xintCn to Cs`,
  - this is then given to `\xintiCstoCv` which produces the list of the convergents (there is also `\xintCstoCv`, but our coefficients being integers we used the infinitesimally faster `\xintiCstoCv`),
  - then the whole list was converted into a sequence of one-line paragraphs, each convergent becomes the argument to a macro printing it together with its decimal expansion with 30 digits after the decimal point.
  - A count register `\cnta` was used to give a line count serving as a visual aid: we could also have done that in an expandable way, but well, let's relax from time to time...

35.  $2.718281828459045235360287471352 \dots = \frac{2124008553358849}{781379079653017}$
36.  $2.718281828459045235360287471352 \dots = \frac{52061284670617417}{19152276311294112}$

The actual computation of the list of all 36 convergents accounts for only 8% of the total time (total time equal to about 5 hundredths of a second in my testing, on my laptop): another 80% is occupied with the computation of the truncated decimal expansions (and the addition of 1 to everything as the formula gives the continued fraction of  $e - 1$ ). One can with no problem compute much bigger convergents. Let's get the 200th convergent. It turns out to have the same first 268 digits after the decimal point as  $e - 1$ . Higher convergents get more and more digits in proportion to their index: the 500th convergent already gets 799 digits correct! To allow speedy compilation of the source of this document when the need arises, I limit here to the 200th convergent (getting the 500th took about 1.2s on my laptop last time I tried, and the 200th convergent is obtained ten times faster).

```

One can also use a centered continued fraction: we get more digits but there are also more computations as the numerators may be either 1 or  $-1$ .

### 33.2 \xintCfrac

- Frac* ★ `\xintCfrac{f}` is a math-mode only, L<sup>A</sup>T<sub>E</sub>X with `amsmath` only, macro which first computes then displays with the help of `\cfrac` the simple continued fraction corresponding to the given fraction (or macro expanding in two steps to one such). It admits an optional argument which may be [l], [r] or (the default) [c] to specify the location of the one's in the numerators of the sub-fractions. Each coefficient is typeset using the `\xintFrac` macro from the `xintfrac` package.

### 33.3 \xintGCFrac

- f* ★ `\xintGCFrac{a+b/c+d/e+f/g+h/...}` uses similarly `\cfrac` to typeset a generalized continued fraction in inline format. It admits the same optional argument as `\xintCfrac`.  
`\[\xintGCFrac {1+\xintPow{1.5}{3}}/{1/7}+{-3/5}/\xintFac {6}\]`

$$1 + \cfrac{3375 \cdot 10^{-3}}{\cfrac{\frac{1}{7} - \frac{3}{5}}{720}}$$

As can be seen this is typesetting macro, although it does proceed to the evaluation of the coefficients themselves. See `\xintGCToF` if you are impatient to see this fraction computed. Numerators and denominators are made arguments to the `\xintFrac` macro.

### 33.4 \xintGCToGCx

- nnf* ★ `\xintGCToGCx{sepa}{sepb}{a+b/c+d/e+f/...+x/y}` returns the list of the coefficients of the generalized continued fraction of *f*, each one within a pair of braces, and separated with the help of *sepa* and *sepb*. Thus

`\xintGCToGCx :;{1+2/3+4/5+6/7}` gives 1:2;3:4;5:6;7

Plain T<sub>E</sub>X+amstex users may be interested in:

```
 $$\xintGCToGCx {+\cfrac{}{}{a+b/\dots}}\endcfrac$$
 $$\xintGCToGCx {+\cfrac{\xintFwOver}{\xintFwOver}{a+b/\dots}}\endcfrac$$
```

### 33.5 \xintFtoCs

- $\frac{\text{Frac}}{f} \star$   $\text{\xintFtoCs}\{f\}$  returns the comma separated list of the coefficients of the simple continued fraction of  $f$ .

```
\[ \xintSignedFrac{-5262046/89233} = [\xintFtoCs{-5262046/89233}] \]
```

$$-\frac{5262046}{89233} = [-59, 33, 27, 100]$$

### 33.6 \xintFtoCx

- $\frac{\text{Frac}}{f} \star$   $\text{\xintFtoCx}\{\text{sep}\}\{f\}$  returns the list of the coefficients of the simple continued fraction of  $f$ , withing group braces and separated with the help of  $\text{sep}$ .

```
 $$\text{\xintFtoCx} \{+\cfrac{1}{\ } \}{f}\endcfrac$$
```

will display the continued fraction in  $\cfrac$  format, with Plain T<sub>E</sub>X and amstex.

### 33.7 \xintFtoGC

- $\frac{\text{Frac}}{f} \star$   $\text{\xintFtoGC}\{f\}$  does the same as  $\text{\xintFtoCx}\{+1/\}\{f\}$ . Its output may thus be used in the package macros expecting such an ‘inline format’. This continued fraction is a *simple* one, not a *generalized* one, but as it is produced in the format used for user input of generalized continued fractions, the macro was called  $\text{\xintFtoGC}$  rather than  $\text{\xintFtoC}$  for example.

```
566827/208524=\xintFtoGC {566827/208524}
```

```
566827/208524=2+1/1+1/2+1/1+1/1+1/4+1/1+1/1+1/6+1/1+1/1+1/8+1/1+1/1+1/11
```

### 33.8 \xintFtoCC

- $\frac{\text{Frac}}{f} \star$   $\text{\xintFtoCC}\{f\}$  returns the ‘centered’ continued fraction of  $f$ , in ‘inline format’.

```
566827/208524=\xintFtoCC {566827/208524}
```

```
566827/208524=3+-1/4+-1/2+1/5+-1/2+1/7+-1/2+1/9+-1/2+1/11
```

```
\[\xintFrac{566827/208524} = \xintGCFrac{\xintFtoCC{566827/208524}}\]
```

$$\frac{566827}{208524} = 3 - \cfrac{1}{4 - \cfrac{1}{2 + \cfrac{1}{5 - \cfrac{1}{2 + \cfrac{1}{7 - \cfrac{1}{2 + \cfrac{1}{9 - \cfrac{1}{2 + \cfrac{1}{11}}}}}}}}$$

### 33.9 \xintFtoCv

- $\frac{\text{Frac}}{f} \star$   $\text{\xintFtoCv}\{f\}$  returns the list of the (braced) convergents of  $f$ , with no separator. To be

treated with `\xintAssignArray` or `\xintListWithSep`.

```
\[\xintListWithSep{\to}{\xintApply\xintFrac{\xintFtoCv{5211/3748}}}\]
```

$$1 \rightarrow \frac{3}{2} \rightarrow \frac{4}{3} \rightarrow \frac{7}{5} \rightarrow \frac{25}{18} \rightarrow \frac{32}{23} \rightarrow \frac{57}{41} \rightarrow \frac{317}{228} \rightarrow \frac{374}{269} \rightarrow \frac{691}{497} \rightarrow \frac{5211}{3748}$$

### 33.10 `\xintFtoCCv`

- Frac* ★ `\xintFtoCCv{f}` returns the list of the (braced) centered convergents of *f*, with no separator. To be treated with `\xintAssignArray` or `\xintListWithSep`.

```
\[\xintListWithSep{\to}{\xintApply\xintFrac{\xintFtoCCv{5211/3748}}}\]
```

$$1 \rightarrow \frac{4}{3} \rightarrow \frac{7}{5} \rightarrow \frac{32}{23} \rightarrow \frac{57}{41} \rightarrow \frac{374}{269} \rightarrow \frac{691}{497} \rightarrow \frac{5211}{3748}$$

### 33.11 `\xintCstoF`

- f* ★ `\xintCstoF{a,b,c,d,...,z}` computes the fraction corresponding to the coefficients, which may be fractions or even macros expanding to such fractions (in two steps). The final fraction may then be highly reducible.

```
\[\xintGCFrac{-1+1/3+1/-5+1/7+1/-9+1/11+1/-13}
=\xintSignedFrac{\xintCstoF{-1,3,-5,7,-9,11,-13}}
=\xintSignedFrac{\xintGCFrac{-1+1/3+1/-5+1/7+1/-9+1/11+1/-13}}\]
```

$$\begin{aligned} -1 + \cfrac{1}{3 + \cfrac{1}{-5 + \cfrac{1}{7 + \cfrac{1}{-9 + \cfrac{1}{11 + \cfrac{1}{-13}}}}} = -\frac{75887}{118187} = -\frac{75887}{118187} \end{aligned}$$

```
\xintGCFrac{{1/2}+1/{1/3}+1/{1/4}+1/{1/5}}=
\xintFrac{\xintCstoF{1/2,1/3,1/4,1/5}}
```

$$\begin{aligned} \frac{1}{2} + \cfrac{1}{\frac{1}{3} + \cfrac{1}{\frac{1}{4} + \cfrac{1}{\frac{1}{5}}}} = \frac{159}{66} \end{aligned}$$

A generalized continued fraction may produce a reducible fraction (`\xintCstoF` tries its best not to accumulate in a silly way superfluous factors but will not do simplifications which would be obvious to a human, like simplification by 3 in the result above).

### 33.12 `\xintCstoCv`

- f* ★ `\xintCstoCv{a,b,c,d,...,z}` returns the list of the corresponding convergents. It is al-

lowed to use fractions as coefficients (the computed convergents have then no reason to be the real convergents of the final fraction). When the coefficients are integers, the convergents are irreducible fractions, but otherwise it is not necessarily the case.

```
\xintListWithSep:{\xintCstoCv{1,2,3,4,5,6}}
 1/1:3/2:10/7:43/30:225/157:1393/972
\xintListWithSep:{\xintCstoCv{1,1/2,1/3,1/4,1/5,1/6}}
 1/1:3/1:9/7:45/19:225/159:1575/729
\[\xintListWithSep{\to}{\xintApply\xintFrac{\xintCstoCv
{\xintPow {-3}{-5},7.3/4.57,\xintCstoF{3/4,9,-1/3}}}\]
 -100000   -72888949   -2700356878
----->----->-----
 243       177390      6567804
```

### 33.13 \xintCstoGC

- f* ★ `\xintCstoGC{a,b,...,z}` transforms a comma separated list (or something expanding to such a list) into an ‘inline format’ continued fraction `{a}+1/{b}+1/...+1/{z}`. The coefficients are just copied and put within braces, without expansion. The output can then be used in `\xintGCFrac` for example.

```
\[\xintGCFrac {\xintCstoGC {-1,1/2,-1/3,1/4,-1/5}}
=\xintSignedFrac {\xintCstoF {-1,1/2,-1/3,1/4,-1/5}}\]
-1 + -----
           1
           -----
           1/2 + -----
                   1
                   -----
                   -1/3 + -----
                           1
                           -----
                           1/4 + -----
                               -1
                               -----
                               5
```

### 33.14 \xintGCToF

- f* ★ `\xintGCToF{a+b/c+d/e+f/g+.....+v/w+x/y}` computes the fraction defined by the inline generalized continued fraction. Coefficients may be fractions but must then be put within braces. They can be macros. The plus signs are mandatory.

```
\[\xintGCFrac {1+\xintPow{1.5}{3}/{1/7}+{-3/5}/\xintFac {6}} =
\xintFrac{\xintGCToF {1+\xintPow{1.5}{3}/{1/7}+{-3/5}/\xintFac {6}}} =
\xintFrac{\xintIrr{\xintGCToF
{1+\xintPow{1.5}{3}/{1/7}+{-3/5}/\xintFac {6}}}}\]
1 + -----
           3375 · 10^-3
           -----
           3579000 = 88629000 = 29543
           -----
           720
\[\xintGCFrac{{1/2}+{2/3}/{4/5}+{1/2}/{1/5}+{3/2}/{5/3}} =
\xintFrac{\xintGCToF {{1/2}+{2/3}/{4/5}+{1/2}/{1/5}+{3/2}/{5/3}}} \]
1/2 + -----
           2
           -----
           4/5 + -----
                   1/2
                   -----
                   1/5 + -----
                           2
                           -----
                           5
                           -----
                           3
```

The macro tries its best not to accumulate superfluous factor in the denominators, but doesn't reduce the fraction to irreducible form before returning it and does not do simplifications which would be obvious to a human.

### 33.15 \xintGCToCv

- f* ★ `\xintGCToCv{a+b/c+d/e+f/g+.....+v/w+x/y}` returns the list of the corresponding convergents. The coefficients may be fractions, but must then be inside braces. Or they may be macros, too.

The convergents will in the general case be reducible. To put them into irreducible form, one needs one more step, for example it can be done with `\xintApply\xintIrr`.

```
\[\xintListWithSep{,}{\xintApply\xintFrac
    {\xintGCToCv{3+{-2}/{7/2}+{3/4}/12+{-56}/3}}}\]
\[\xintListWithSep{,}{\xintApply\xintFrac{\xintApply\xintIrr
    {\xintGCToCv{3+{-2}/{7/2}+{3/4}/12+{-56}/3}}}}\]
```

$$3, \frac{17}{7}, \frac{834}{342}, \frac{1306}{542}$$

$$3, \frac{17}{7}, \frac{139}{57}, \frac{653}{271}$$

### 33.16 \xintCtoF

- num<sub>x</sub> f* ★ `\xintCtoF{N}{\macro}` computes the fraction *f* having coefficients  $c(j)=\macro{j}$  for  $j=0, 1, \dots, N$ . The *N* parameter is given to a `\numexpr`. The values of the coefficients, as returned by `\macro` do not have to be positive, nor integers, and it is thus not necessarily the case that the original  $c(j)$  are the true coefficients of the final *f*.

```
\def\macro #1{\the\numexpr 1+#1*\relax}\xintCtoF {5}{\macro}
72625/49902[0]
```

### 33.17 \xintGCntoF

- num<sub>x</sub> ff* ★ `\xintGCntoF{N}{\macroA}{\macroB}` returns the fraction *f* corresponding to the inline generalized continued fraction  $a_0+b_0/a_1+b_1/a_2+\dots+b_{(N-1)}/a_N$ , with  $a(j)=\macroA{j}$  and  $b(j)=\macroB{j}$ . The *N* parameter is given to a `\numexpr`.

$$1 + \cfrac{1}{2 - \cfrac{1}{3 + \cfrac{1}{1 - \cfrac{1}{2 + \cfrac{1}{3 - \cfrac{1}{1}}}}}} = \frac{39}{25}$$

There is also `\xintGCntoGC` to get the ‘inline format’ continued fraction. The previous display was obtained with:

```
\def\coeffA #1{\the\numexpr #1+4-3*((#1+2)/3)\relax }%
```

```
\def\coeffB #1{\xintMON{#1} \% (-1)^n
\[\xintGCFrac{\xintGCntoGC {6}{\coeffA}{\coeffB}}
= \xintFrac{\xintGCntoF {6}{\coeffA}{\coeffB}}\]
```

### 33.18 **\xintCntrCs**

- num** *f* ★  $\xintCntrCs{N}{\macro}$  produces the comma separated list of the corresponding coefficients, from  $n=0$  to  $n=N$ . The  $N$  is given to a `\numexpr`.

```
\def\macro #1{\the\numexpr 1+#1*\#1\relax}
\xintCntrCs {5}{\macro}->1,2,5,10,17,26
\[\xintFrac{\xintCntrF {5}{\macro}}=\xintFrac{\xintCntrF {5}{\macro}}\]
```

$$\frac{72625}{49902} = 1 + \cfrac{1}{2 + \cfrac{1}{5 + \cfrac{1}{10 + \cfrac{1}{17 + \cfrac{1}{26}}}}}$$

### 33.19 **\xintCntrGC**

- num** *f* ★  $\xintCntrGC{N}{\macro}$  evaluates the  $c(j)=\macro{j}$  from  $j=0$  to  $j=N$  and returns a continued fraction written in inline format:  $\{c(0)\}+1/\{c(1)\}+1/\dots+1/\{c(N)\}$ . The parameter  $N$  is given to a `\numexpr`. The coefficients, after expansion, are, as shown, being enclosed in an added pair of braces, they may thus be fractions.

```
\def\macro #1{\the\numexpr\ifodd#1 -1-#1\else1+#1\fi\relax%
\the\numexpr 1+#1*\#1\relax}
\edef\x{\xintCntrGC {5}{\macro}}\meaning\x
macro:->\{1/1\}+1/\{-2/2\}+1/\{3/5\}+1/\{-4/10\}+1/\{5/17\}+1/\{-6/26\}
\[\xintGCFrac{\xintCntrGC {5}{\macro}}\]
```

$$1 + \cfrac{1}{\frac{-2}{2} + \cfrac{1}{\frac{3}{5} + \cfrac{1}{\frac{-4}{10} + \cfrac{1}{\frac{5}{17} + \cfrac{1}{\frac{-6}{26}}}}}}$$

### 33.20 **\xintGCntoGC**

- num** *ff* ★  $\xintGCntoGC{N}{\macroA}{\macroB}$  evaluates the coefficients and then returns the corresponding  $\{a_0\}+\{b_0\}/\{a_1\}+\{b_1\}/\{a_2\}+\dots+\{b_{(N-1)}\}/\{a_N\}$  inline generalized fraction.  $N$  is given to a `\numexpr`. As shown, the coefficients are enclosed into added pairs of braces, and may thus be fractions.

```
#1*#1*#1+1\relax%
```

```
\def\bn #1{\the\numexpr \xintiiMON{#1}*(#1+1)\relax}%
$\xintGCntoGC {5}{\an}{\bn}=\xintGCFrac {\xintGCntoGC {5}{\an}{\bn}} = %
\displaystyle\xintFrac {\xintGCntoF {5}{\an}{\bn}}\$\\par
1 + 1/2 + -2/9 + 3/28 + -4/65 + 5/126 = 1 + \cfrac{1}{2 - \cfrac{3}{9 + \cfrac{4}{28 - \cfrac{5}{65 + \cfrac{}{126}}}}} = \cfrac{5797655}{3712466}
```

### 33.21 **\xintiCstoF**, **\xintiGCToF**, **\xintiCstoCv**, **\xintiGCToCv**

The same as the corresponding macros without the ‘i’, but for integer-only input. Infinitely faster; to notice the higher efficiency one would need to use them with an input having (at least) hundreds of coefficients.

### 33.22 **\xintGCToGC**

- f* ★ **\xintGCToGC{a+b/c+d/e+f/g+.....+v/w+x/y}** expands (with the usual meaning) each one of the coefficients and returns an inline continued fraction of the same type, each expanded coefficient being enclosed withing braces.

```
{6}+\xintCstoF {2,-7,-5}/16} \meaning\x
macro:->{1}+{3375/1[-3]}/{1/7}+{-3/5}/{720}+{67/36}/{16}
```

To be honest I have, it seems, forgotten why I wrote this macro in the first place.

## 34 Package `xinttools` implementation

Release 1.09g splits off `xinttools.sty` from `xint.sty`.

#### 34.1 Catcodes, $\varepsilon$ -**T<sub>E</sub>X** and reload detection

The method for package identification and reload detection is copied verbatim from the packages by HEIKO OBERDIEK (with some modifications starting with release 1.09b).

The method for catcodes was also inspired by these packages, we proceed slightly differently.

Starting with version 1.06 of the package, also ‘ must be catcode-protected, because we replace everywhere in the code the twice-expansion done with `\expandafter` by the systematic use of `\romannumeral-‘0`.

Starting with version 1.06b I decide that I suffer from an indigestion of @ signs, so I replace them all with underscores \_, à la L<sup>A</sup>T<sub>E</sub>X3.

Release 1.09b is more economical: some macros are defined already in `xint.sty` (now `xinttools.sty`) and re-used in other modules. All catcode changes have been unified and `\XINT_storecatcodes` will be used by each module to redefine `\XINT_restorecatcodes_endinput` in case catcodes have changed in-between the loading of `xint.sty` (now `xinttools.sty`) and the module (not very probable but...).

```

## 34.2 Package identification

Inspired from HEIKO OBERDIEK's packages. Modified in 1.09b to allow re-use in the other modules. Also I assume now that if `\ProvidesPackage` exists it then does define `\ver@<pkgname>.sty`, code of HO for some reason escaping me (compatibility with LaTeX 2.09 or other things ??) seems to set extra precautions.

1.09c uses e-TEX `\ifdefined`.

```

117 \ifdefined\ProvidesPackage
118   \let\XINT_providespackage\relax
119 \else
120   \def\XINT_providespackage #1#2[#3]%
121     {\immediate\write-1{Package: #2 #3}%
122      \expandafter\xdef\csname ver@#2.sty\endcsname{#3}}%
123 \fi
124 \XINT_providespackage
125 \ProvidesPackage {xinttools}%
126 [2013/12/18 v1.09i Expandable and non-expandable utilities (jfB)]%

```

## 34.3 Token management, constants

In 1.09e `\xint_undef` replaced everywhere by `\xint_bye`. Release 1.09h makes most everything `\long`.

```

127 \long\def\xint_gobble_      {}%

183 }%

```

### 34.8 \xintRevWithBraces

New with 1.06. Makes the expansion of its argument and then reverses the resulting tokens or braced tokens, adding a pair of braces to each (thus, maintaining it when it was already there).

As in some other places, 1.09e replaces \Z by \xint\_bye, although here it is just for coherence of notation as \Z would be perfectly safe. The reason for \xint\_relax, here and in other locations, is in case #1 expands to nothing, the \romannumeral-`0 must be stopped

```

### 34.9 `\xintLength`

`\xintLength` does NOT expand its argument.  
 1.09g adds the missing `\xintlength`, which was previously called `\XINT_length`, and suppresses `\XINT_Length`  
 1.06: improved code is roughly 20% faster than the one from earlier versions.  
 1.09a, `\xintnum` inserted. 1.09e: `\Z->\xint_bye` as this is called from `\xintNthElt`, and there it was necessary not to use `\Z`. Later use of `\Z` and `\W` perfectly safe here.

```

### 34.10 \xintZapFirstSpaces

1.09f, written [2013/11/01].

```

256 \def\xintZapFirstSpaces {\romannumeral0\xintzapfirstspaces }%
defined via an \edef in order to inject space tokens inside.

257 \long\edef\xintzapfirstspaces #1%
258   {\noexpand\xint_zapbsp_a \space #1\space\space\noexpand\xint_bye\xint_relax }%
259 \xint_firstofone {\long\def\xint_zapbsp_a #1 } %<- space token here
260 {%

```

If the original #1 started with a space, here #1 will be in fact empty, so the effect will be to remove precisely one space from the original, because the first two space tokens are matched to the ones of the macro parameter text. If the original #1 did not start with a space then the #1 will be this original #1, with its added first space, up to the first <sp><sp> found. The added initial space will stop later the \romannumeral0. And in \xintZapLastSpaces we also carried along a space in order to be able to mix the two codes in \xintZapSpaces. Testing for \emptiness of #1 is NOT done with an \if test because #1 may contain \if, \fi things (one could use a \detokenize method), and also because xint.sty has a style of its own for doing these things...

```

261   \XINT_zapbsp_again? #1\xint_bye\xint_zapbsp_b {#1}%

```

### 34 Package *xinttools* implementation

The #1 above is thus either empty, or it starts with a (char 32) space token followed with a non (char 32) space token and at any rate #1 is protected from brace stripping. It is assumed that the initial input does not contain space tokens of other than 32 as character code.

```
262 }%
263 \long\def\XINT_zapbsp_again? #1{\xint_bye #1\XINT_zapbsp_again }%
```

In the "empty" situation above, here #1=\xint\_bye, else #1 could be some brace things, but unbracing will anyhow not reveal any \xint\_bye. When we do below \XINT\_zapbsp\_again we recall that we have stripped two spaces out of <sp><original #1>, so we have one <sp> less in #1, and when we loop we better not forget to reinsert one initial <sp>.

```
264 \edef\XINT_zapbsp_again\XINT_zapbsp_b #1{\noexpand\XINT_zapbsp_a\space }%
```

We now have now gotten rid of the initial spaces, but #1 perhaps extend only to some initial chunk which was delimited by <sp><sp>.

```
265 \long\def\XINT_zapbsp_b #1#2\xint_relax
266   {\XINT_zapbsp_end? #2\XINT_zapbsp_e\empty #2{#1}}%
```

If the initial chunk up to <sp><sp> (after stripping away the first spaces) was maximal, then #2 above is some spaces followed by \xint\_bye, so in the \XINT\_zapbsp\_end? below it appears as \xint\_bye, else the #1 below will not be nor give rise after brace removal to \xint\_bye. And then the original \xint\_bye in #2 will have the effect that all is swallowed and we continue with \XINT\_zapbsp\_e. If the chunk was maximal, then the #2 above contains as many space tokens as there were originally at the end.

```
267 \long\def\XINT_zapbsp_end? #1{\xint_bye #1\XINT_zapbsp_end }%
```

The #2 starts with a space which stops the \romannumeral. The #1 contains the same number of space tokens there was originally.

```
268 \long\def\XINT_zapbsp_end\XINT_zapbsp_e\empty #1\xint_bye #2{#2#1}%
```

Here the initial chunk was not maximal. So we need to get a second piece all the way up to \xint\_bye, we take this opportunity to remove the two initially added ending space tokens. We inserted an \empty to prevent brace removal. The \expandafter get rid of the \empty.

```
269 \xint_firstofone{\long\def\XINT_zapbsp_e #1 } \xint_bye
270   {\expandafter\XINT_zapbsp_f \expandafter{#1}}%
```

Let's not forget when we glue to reinsert the two intermediate space tokens.

```
271 \long\edef\XINT_zapbsp_f #1#2{#2\space\space #1}%
```

### 34.11 \xintZapLastSpaces

1.09f, written [2013/11/01].

```
272 \def\xintZapLastSpaces {\romannumeral0\xintzaplastspaces }%
```

Next macro is defined via an \edef for the space tokens.

```
273 \long\edef\xintzaplastspaces #1{\noexpand\XINT_zapesp_a {\space}\noexpand\empty
274           #1\space\space\noexpand\xint_bye \xint_relax}%
```

This creates a delimited macro with two space tokens:

```
275 \xint_firstofone {\long\def\XINT_zapesp_a #1#2 } %<- second space here
276   {\expandafter\XINT_zapesp_b\expandafter{#2}{#1}}%
```

The \empty from \xintzaplastspaces is to prevent brace removal in the #2 above.  
The \expandafter chain removes it.

```
277 \long\def\XINT_zapesp_b #1#2#3\xint_relax
278   {\XINT_zapesp_end? #3\XINT_zapesp_e {#2#1}\empty #3\xint_relax }%
```

When we have reached the ending space tokens, #3 is a bunch of spaces followed by \xint\_bye. So the #1 below will be \xint\_bye. In all other cases #1 can not be \xint\_bye nor can it give birth to it via brace stripping.

```
279 \long\def\XINT_zapesp_end? #1{\xint_bye #1\XINT_zapesp_end }%
```

We are done. The #1 here has accumulated all the previous material. It started with a space token which stops the \romannumeral0. The reason for the space is the recycling of this code in \xintZapSpaces.

```
280 \long\def\XINT_zapesp_end\XINT_zapesp_e #1#2\xint_relax {#1}%
```

We haven't yet reached the end, so we need to re-inject two space tokens after what we have gotten so far. Then we loop. We might wonder why in \XINT\_zapesp\_b we scooped everything up to the end, rather than trying to test if the next thing was a bunch of spaces followed by \xint\_bye\xint\_relax. But how can we expandably examine what comes next? if we pick up something as undelimited parameter token we risk brace removal and we will never know about it so we cannot reinsert correctly; the only way is to gather a delimited macro parameter and be sure some token will be inside to forbid brace removal. I do not see (so far) any other way than scooping everything up to the end. Anyhow, 99% of the use cases will NOT have <sp><sp> inside!.

```
281 \long\edef\XINT_zapesp_e #1{\noexpand \XINT_zapesp_a {#1\space\space}}%
```

### 34.12 \xintZapSpaces

1.09f, written [2013/11/01].

```
282 \def\xintZapSpaces {\romannumeral0\xintzapspaces }%
```

We start like \xintZapStartSpaces.

```
283 \long\edef\xintzapspaces #1%
284   {\noexpand\XINT_zapsp_a \space #1\space\space\noexpand\xint_bye\xint_relax}%
```

Once the loop stripping the starting spaces is done, we plug into the \xintZapLastSpaces code via \XINT\_zapesp\_b. As our #1 will always have an initial space, this is why we arranged code of \xintZapLastSpaces to do the same.

```
285 \xint_firstofone {\long\def\XINT_zapsp_a #1 } %<- space token here
286 {%
287   \XINT_zapsp_again? #1\xint_bye\XINT_zapesp_b {#1}{}}%
288 }%

### 34.14 \xintCSVtoList, \xintCSVtoListNonStripped

\xintCSVtoList transforms a,b,...,z into {a}{b}...{z}. The comma separated list may be a macro which is first expanded (protect the first item with a space if it is not to be expanded). First included in release 1.06. Here, use of \Z (and \R) perfectly safe.

[2013/11/02]: Starting with 1.09f, automatically filters items through \xintZapSpacesB to strip off all spaces around commas, and spaces at the start and end of the list. The original is kept as \xintCSVtoListNonStripped, and is faster. But ... it doesn't strip spaces.

```

### 34.15 \xintListWithSep

`\xintListWithSep {\sep}{\{a\}{b}\dots\{z\}}` returns a `\sep b \sep \dots \sep z`  
 Included in release 1.04. The 'sep' can be `\par`'s: the macro `xintlistwithsep`  
 etc... are all declared long. 'sep' does not have to be a single token. It is not  
 expanded. The list may be a macro and it is expanded. 1.06 modifies the 'feature'  
 of returning sep if the list is empty: the output is now empty in that case. (sep  
 was not used for a one element list, but strangely it was for a zero-element list).

Use of `\Z` as delimiter was objectively an error, which I fix here in 1.09e, now  
 the code uses `\xint_bye`.

```

```

### 34.16 \xintNthElt

`\xintNthElt {i}{\{a\}{b}\dots\{z\}}` (or 'tokens' abcd...z) returns the i th element  
 (one pair of braces removed). The list is first expanded. First included in release  
 1.06. With 1.06a, a value of i = 0 (or negative) makes the macro return the length.

This is different from `\xintLen` which is for numbers (checks sign) and different from `\xintLength` which does not first expand its argument. With 1.09b, only  $i=0$  gives the length, negative values return the  $i$  th element from the end. 1.09c has some slightly less quick initial preparation (if #2 is very long, not good to have it twice), I wanted to respect the `noexpand` directive in all cases, and the alternative would be to define more macros.

At some point I turned the `\W`'s into `\xint_relax`'s but forgot to modify accordingly `\XINT_nthelt_finish`. So in case the index is larger than the number of items the macro returned was an `\xint_relax` token rather than nothing. Fixed in 1.09e. I also take the opportunity of this fix to replace uses of `\Z` by `\xint_bye`. (and as a result I must do the change also in `\XINT_length_loop` and related macros).

```

### 34.18 \xintApplyUnbraced

`\xintApplyUnbraced {\macro}{\{a\}\{b\}\dots\{z\}}` returns `\macro{a}\dots\macro{z}` where each instance of `\macro` is expanded using `\romannumeral`0`. The second argument may be a macro as it is first expanded itself (fully). No braces are added: this allows for example a non-expandable `\def` in `\macro`, without having to do `\gdef`. The list is first expanded. Introduced with release 1.06b. Define `\macro` to start with a space if it is not expandable or its execution should be delayed only when all of `\macro{a}\dots\macro{z}` is ready.

Modified in 1.09e to use `\xint_bye` rather than `\Z`.

```

### 34.19 \xintSeq

1.09c. Without the optional argument puts stress on the input stack, should not be used to generated thousands of terms then. Here also, let's use `\xint_bye` rather than `\Z` as delimiter (1.09e; necessary change as `#1` is used prior to being expanded, thus `\Z` might very well arise here as a macro).

### 34.22 \XINT\_xflet

1.09e [2013/10/29]: we expand fully unbraced tokens and swallow arising space tokens until the dust settles. For treating cases {<blank>\x<blank>\y...}, with guaranteed expansion of the \x (which may itself give space tokens), a simpler approach is possible with doubled \romannumeral-'0, this is what I first did, but it had the feature that <sptoken><sptoken>\x would not expand the \x. At any rate, <sptoken>'s before the list terminator z were all correctly moved out of the way, hence the stuff was robust for use in (the then current versions of) \xintApplyInline and \xintFor. Although \*two\* space tokens would need devilishly prepared input, nevertheless I decided to also survive that, so here the method is a bit more complicated. But it simplifies things on the caller side.

```

### 34.23 \xintApplyInline

1.09a: `\xintApplyInline\macro{{a}{b}...{z}}` has the same effect as executing `\macro{a}` and then applying again `\xintApplyInline` to the shortened list `{b}...{z}` until nothing is left. This is a non-expandable command which will result in quicker code than using `\xintApplyUnbraced`. It expands (fully) its second (list) argument first, which may thus be encapsulated in a macro.

Release 1.09c has a new `\xintApplyInline`: the new version, while not expandable, is designed to survive when the applied macro closes a group, as is the case in alignments when it contains a & or `\``. It uses catcode 3 Z as list terminator. Don't use it among the list items.

1.09d: the bug which was discovered in `\xintFor*` regarding space tokens at the very end of the item list also was in `\xintApplyInline`. The new version will expand unbraced item elements and this is in fact convenient to simulate insertion of lists in others.

1.09e: the applied macro is allowed to be long, with items (or the first fixed arguments of the macro, passed together with it as #1 to `\xintApplyInline`) containing explicit `\par`'s. (1.09g: some missing `\long`'s added)

1.09f: terminator used to be z, now Z (still catcode 3).

### 34.24 `\xintFor`, `\xintFor*`, `\xintBreakFor`, `\xintBreakForAndDo`

1.09c [2013/10/09]: a new kind of loop which uses macro parameters #1, #2, #3, #4 rather than macros; while not expandable it survives executing code closing groups, like what happens in an alignment with the & character. When inserted in a macro for later use, the # character must be doubled.

The non-star variant works on a csv list, which it expands once, the star variant works on a token list, expanded fully.

1.09d: [2013/10/22] `\xintFor*` crashed when a space token was at the very end of the list. It is crucial in this code to not let the ending Z be picked up as a macro parameter without knowing in advance that it is its turn. So, we conscientiously clean out of the way space tokens, but also we ff-expand with `\romannumeral-`0` (unbraced) items, a process which may create new space tokens, so it is iterated. As unbraced items are expanded, it is easy to simulate insertion of a list in another. Unbraced items consecutive to an even (non-zero) number of space tokens will not get expanded.

1.09e: [2013/10/29] does this better, no difference between an even or odd number of explicit consecutive space tokens. Normal situations anyhow only create at most one space token, but well. There was a feature in `\xintFor` (not `\xintFor*`) from 1.09c that it treated an empty list as a list with one, empty, item. This feature is kept in 1.09e, knowingly... Also, macros are made long, hence the iterated text may contain `\par` and also the looped over items. I thought about providing some macro expanding to the loop count, but as the `\xintFor` is not expandable anyhow, there is no loss of generality if the iterated commands do themselves the bookkeeping using a count or a LaTeX counter, and deal with nesting or other problems. I can't do \*everything\*!

1.09e adds `\XINT_forever` with `\xintintegers`, `\xintdimensions`, `\xintrationals` and `\xintBreakFor`, `\xintBreakForAndDo`, `\xintifForFirst`, `\xintifForLast`. On this occasion `\xint_firstoftwo` and `\xint_secondoftwo` are made long.

1.09f: rewrites large parts of `\xintFor` code in order to filter the comma separated list via `\xintCSVtoList` which gets rid of spaces. Compatibility with `\XINT_forever`, the necessity to prevent unwanted brace stripping, and shared code with `\xintFor*`, make this all a delicate balancing act. The #1 in `\XINT_for_forever?` has an initial space token which serves two purposes: preventing brace stripping, and stopping the expansion made by `\xintcsvtolist`. If the `\XINT_forever` branch is taken, the added space will not be a problem there.

1.09f rewrites (2013/11/03) the code which now allows all macro parameters from #1 to #9 in `\xintFor`, `\xintFor*`, and `\XINT_forever`.

The 1.09f `\xintFor` and `\xintFor*` modified the value of `\count` 255 which was silly, 1.09g used `\XINT_count`, but requiring a `\count` only for that was also silly, 1.09h just uses `\numexpr` (all of that was only to get rid simply of a possibly space in #2...).

### 34.25 \XINT\_forever, \xintintegers, \xintdimensions, \xintrationals

New with 1.09e. But this used inadvertently  $\xintiadd/\xintimul$  which have the unnecessary  $\xintnum$  overhead. Changed in 1.09f to use  $\xintiiadd/\xintiimul$  which do not have this overhead. Also 1.09f has  $\xintZapSpacesB$  which helps getting rid of spaces for the  $\xintrationals$  case (the other cases end up inside a  $\numexpr$ , or  $\dimexpr$ , so not necessary).

### 34.26 \xintForpair, \xintForthree, \xintForfour

1.09c: I don't know yet if {a}{b} is better for the user or worse than (a,b). I prefer the former. I am not very motivated to deal with spaces in the (a,b) approach which is the one (currently) followed here.

[2013/11/02] 1.09f: I may not have been very motivated in 1.09c, but since then I developped the \xintZapSpaces/\xintZapSpacesB tools (much to my satisfaction). Based on this, and better parameter texts, \xintForpair and its cousins now handle spaces very satisfactorily (this relies partly on the new \xintCSVtoList which makes use of \xintZapSpacesB). Does not share code with \xintFor anymore.

[2013/11/03] 1.09f: \xintForpair extended to accept #1#2, #2#3 etc... up to #8#9, \xintForthree, #1#2#3 up to #7#8#9, \xintForfour id.

```

### 34.27 *\xintAssign*, *\xintAssignArray*, *\xintDigitsOf*

```
\xintAssign {a}{b}...{z}\to\A\B...\Z,
\xintAssignArray {a}{b}...{z}\to\U
```

version 1.01 corrects an oversight in 1.0 related to the value of *\escapechar* at the time of using *\xintAssignArray* or *\xintRelaxArray*. These macros are non-expandable.

In version 1.05a I suddenly see some incongruous *\expandafter*'s in (what is called now) *\XINT\_assignarray\_end\_c*, which I remove.

Release 1.06 modifies the macros created by *\xintAssignArray* to feed their argument to a *\numexpr*. Release 1.06a detects an incredible typo in 1.01, (bad copy-paste from *\xintRelaxArray*) which caused *\xintAssignArray* to use #1 rather than the #2 as in the correct earlier 1.0 version!!! This went through undetected because *\xint\_arrayname*, although weird, was still usable: the probability to overwrite something was almost zero. The bug got finally revealed doing *\xintAssignArray {}{}{}{} \to\Stuff*.

With release 1.06b an empty argument (or expanding to empty) to *\xintAssignArray* is ok.

1.09h simplifies the coding of *\xintAssignArray* (no more *\_end\_a*, *\_end\_b*, etc...), and no use of a *\count* register anymore, and uses *\xintiloop* in *\xintRelaxArray*. Furthermore, macros are made long.

1.09i allows an optional parameter *\xintAssign [oo]* for example, then *\oodef* rather than *\edef* is used. Idem for *\xintAssignArray*. However in the latter case, the global variant is not available, one should use *\globaldefs* for that.

## 35 Package *xint* implementation

With release 1.09a all macros doing arithmetic operations and a few more apply systematically `\xintnum` to their arguments; this adds a little overhead but this is more convenient for using count registers even with infix notation; also this is what `xintfrac.sty` did all along. Simplifies the discussion in the documentation too.

### 35.1 Catcodes, $\varepsilon$ -**T<sub>E</sub>X** and reload detection

The code for reload detection is copied from HEIKO OBERDIEK's packages, and adapted here to check for previous loading of the master **xint** package.

The method for catcodes is slightly different, but still directly inspired by these packages.

### 35.6 \xintRev

\xintRev: expands fully its argument \romannumeral-‘0, and checks the sign. However this last aspect does not appear like a very useful thing. And despite the fact that a special check is made for a sign, actually the input is not given to \xintnum, contrarily to \xintLen. This is all a bit incoherent. Should be fixed.

```

114 \def\xintRev {\romannumeral0\xintrev }%
115 \def\xintrev #1%
116 {%

### 35.11 \xintNum

For example \xintNum {-----00000000000003}  
 1.05 defines \xintiNum, which allows redefinition of \xintNum by xintfrac.sty  
 Slightly modified in 1.06b (\R->\xint\_relax) to avoid initial re-scan of input  
 stack (while still allowing empty #1). In versions earlier than 1.09a it was en-  
 tirely up to the user to apply \xintnum; starting with 1.09a arithmetic macros of  
 xint.sty (like earlier already xintfrac.sty with its own \xintnum) make use of  
 \xintnum. This allows arguments to be count registers, or even \numexpr arbitrary  
 long expressions (with the trick of braces, see the user documentation).

```

377         \else\expandafter\xint_firstofthree_afterstop
378     \fi
379 }%

```

### 35.15 \XINT\_\_SgnFork

1.09i. Used internally, #1 must expand to \m@ne, \z@, or \@ne or equivalent. Does not insert a \romannumeral0 stopping space token.

```

380 \def\XINT__SgnFork #1%
381 {%
382     \ifcase #1\expandafter\xint_secondofthree

```

```

383      \or\expandafter\xint_thirddofthree
384      \else\expandafter\xint_firstofthree
385  \fi
386 }%

```

### 35.16 \xintifSgn

Expandable three-way fork added in 1.09a. Branches expandably depending on whether  $<0$ ,  $=0$ ,  $>0$ . Choice of branch guaranteed in two steps.

The use of `\romannumeral0\xintsgn` rather than `\xintSgn` is for matters related to the transformation of the ternary operator : in `\xintNewExpr`. I hope I have explained there the details because right now off hand I can't recall why.

1.09i has `\xint_firstofthreeafterstop` etc for faster expansion.

```

387 \def\xintifSgn {\romannumeral0\xintifsgn }%
388 \def\xintifsgn #1%
389 {%
390   \ifcase \romannumeral0\xintsgn{#1}

ARITHMETIC OPERATIONS: ADDITION, SUBTRACTION, SUMS, MULTIPLICATION, PRODUCTS, FACTORIAL, POWERS, EUCLIDEAN DIVISION.

Release 1.03 re-organizes sub-routines to facilitate future developments: the diverse variants of addition, with diverse conditions on inputs and output are

### 35 Package *xint* implementation

first listed; they will be used in multiplication, or in the summation, or in the power routines. I am aware that the commenting is close to non-existent, sorry about that.

ADDITION I: \XINT\_add\_A  
 INPUT:  
 $\text{romannumeral0}\backslash\text{XINT\_add\_A } 0\{\} <\!\!N1\!\!>\backslash W\backslash X\backslash Y\backslash Z <\!\!N2\!\!>\backslash W\backslash X\backslash Y\backslash Z$   
 1.  $<\!\!N1\!\!>$  et  $<\!\!N2\!\!>$  renversés  
 2. de longueur 4n (avec des leading zéros éventuels)  
 3. l'un des deux ne doit pas se terminer par 0000  
 [Donc on peut avoir 0000 comme input si l'autre est >0 et ne se termine pas en 0000 bien sûr]. On peut avoir l'un des deux vides. Mais alors l'autre ne doit être ni vide ni 0000.

OUTPUT: la somme  $<\!\!N1\!\!> + <\!\!N2\!\!>$ , ordre normal, plus sur 4n, pas de leading zeros La procédure est plus rapide lorsque  $<\!\!N1\!\!>$  est le plus court des deux.

Nota bene: (30 avril 2013). J'ai une version qui est deux fois plus rapide sur des nombres d'environ 1000 chiffres chacun, et qui commence à être avantageuse pour des nombres d'au moins 200 chiffres. Cependant il serait vraiment compliqué d'en étendre l'utilisation aux emplois de l'addition dans les autres routines, comme celle de multiplication ou celle de division; et son implémentation ajouterait au minimum la mesure de la longueur des summands.

```

```

Addition II: \XINT\_addr\_A.

INPUT: \romannumerical0\XINT\_addr\_A 0{}<N1>\W\X\Y\Z <N2>\W\X\Y\Z

Comme \XINT\_add\_A, la différence principale c'est qu'elle donne son résultat aussi \*sur 4n\*, renversé. De plus cette variante accepte que l'un ou même les deux inputs soient vides. Utilisé par la sommation et par la division (pour les quotients). Et aussi par la multiplication d'ailleurs.

INPUT: comme pour \XINT\_add\_A

1. <N1> et <N2> renversés

### 35 Package *xint* implementation

2. de longueur 4n (avec des leading zéros éventuels)  
 3. l'un des deux ne doit pas se terminer par 0000  
 OUTPUT: la somme <N1>+<N2>, \*aussi renversée\* et \*sur 4n\*

### 35.42 \xintMax

The rationale is that it is more efficient than using \xintCmp. 1.03 makes the code a tiny bit slower but easier to re-use for fractions. Note: actually since 1.08a code for fractions does not all reduce to these entry points, so perhaps I should revert the changes made in 1.03. Release 1.09a has \xintnum added into \xintiMax.

### 35.48 \xintSum, \xintSumExpr

\xintSum {{a}{b}...{z}}  
\xintSumExpr {a}{b}...{z}\relax

1.03 (drastically) simplifies and makes the routines more efficient (for big computations). Also the way \xintSum and \xintSumExpr ... \relax are related. has been modified. Now \xintSumExpr {z} \relax is accepted input when {z} expands to a list of braced terms (prior only \xintSum {{z}} or \xintSum {z} was possible).

1.09a does NOT add the \xintnum overhead. 1.09h renames \xintiSum to \xintiiSum to correctly reflect this.

```

MULTIPLICATION
Ici #1#2 = 2e input et #3#4 = 1er input
Release 1.03 adds some overhead to first compute and compare the lengths of the two
inputs. The algorithm is asymmetrical and whether the first input is the longest
or the shortest sometimes has a strong impact. 50 digits times 1000 digits used
to be 5 times faster than 1000 digits times 50 digits. With the new code, the user
input order does not matter as it is decided by the routine what is best. This is
important for the extension to fractions, as there is no way then to generally
control or guess the most frequent sizes of the inputs besides actually computing
their lengths.

Routine de multiplication principale (attention délimiteurs modifiés pour 1.08)  
Le résultat partiel est toujours maintenu avec significatif à droite et il a un  
nombre multiple de 4 de chiffres

### 35 Package *xint* implementation

\romannumeral0\XINT\_mul\_enter <N1>\Z\Z\Z\Z <N2>\W\W\W\W  
 avec <N1> \*renversé\*, \*longueur 4n\* (zéros éventuellement ajoutés au-delà du chiffre le plus significatif) et <N2> dans l'ordre \*normal\*, et pas forcément longueur 4n. pas de signes.

Pour 1.08: dans \XINT\_mul\_enter et les modifs de 1.03 qui filtrent les courts, on pourrait croire que le second opérande a au moins quatre chiffres; mais le problème c'est que ceci est appelé par \XINT\_sqrt. Et de plus \XINT\_sqrt est utilisé dans la nouvelle routine d'extraction de racine carrée: je ne veux pas rajouter l'overhead à \XINT\_sqrt de voir si a longueur est au moins 4. Dilemme donc. Il ne semble pas y avoir d'autres accès directs (celui de big fac n'est pas un problème). J'ai presque été tenté de faire du 5x4, mais si on veut maintenir les résultats intermédiaires sur 4n, il y a des complications. Par ailleurs, je modifie aussi un petit peu la façon de coder la suite, compte tenu du style que j'ai développé ultérieurement. Attention terminaison modifiée pour le deuxième opérande.

```

Ici, le deuxième nombre se termine. Fin du calcul. On utilise la variante `\xint_addm_A` de l'addition car on sait que le deuxième terme est au moins aussi long que le premier. Lorsque le multiplicateur avait longueur  $4n$ , la dernière addition a fourni le résultat à l'envers, il faut donc encore le renverser.

```

1904 }%
Variante de la Multiplication
\romannumeral0\XINT_mulr_enter <N1>\Z\Z\Z\Z <N2>\W\W\W\W
Ici <N1> est à l'envers sur 4n, et <N2> est à l'endroit, pas sur 4n, comme dans
\XINT_mul_enter, mais le résultat est lui-même fourni *à l'envers*, sur *4n* (en
faisant attention de ne pas avoir 0000 à la fin).
Utilisé par le calcul des puissances. J'ai modifié dans 1.08 sur le modèle de la
nouvelle version de \XINT_mul_enter. Je pourrais économiser des macros et fu-
sionner \XINT_mul_enter et \XINT_mulr_enter. Une autre fois.

## 35.52 \xintPrd, \xintPrdExpr

```
\xintPrd {{a}...{z}}
\xintPrdExpr {a}...{z}\relax
```

Release 1.02 modified the product routine. The earlier version was faster in situations where each new term is bigger than the product of all previous terms, a situation which arises in the algorithm for computing powers. The 1.02 version was changed to be more efficient on big products, where the new term is small compared to what has been computed so far (the power algorithm now has its own product routine).

Finally, the 1.03 version just simplifies everything as the multiplication now decides what is best, with the price of a little overhead. So the code has been dramatically reduced here.

In 1.03 I also modify the way `\xintPrd` and `\xintPrdExpr ... \relax` are related. Now `\xintPrdExpr \z \relax` is accepted input when `\z` expands to a list of braced terms (prior only `\xintPrd {\z}` or `\xintPrd \z` was possible).

In 1.06a I suddenly decide that `\xintProductExpr` was a silly name, and as the package is new and certainly not used, I decide I may just switch to `\xintPrdExpr` which I should have used from the beginning.

1.09a does NOT add the `\xintnum` overhead. 1.09h renames `\xintiPrd` to `\xintiiPrd` to correctly reflect this.

### 35.54 \xintFac

Modified with 1.02 and again in 1.03 for greater efficiency. I am tempted, here and elsewhere, to use \ifcase\XINT\_Geq {#1}{1000000000} rather than \ifnum\xintLength {#1}>9 but for the time being I leave things as they stand. With release 1.05, rather than using \xintLength I opt finally for direct use of \numexpr (which will throw a suitable number too big message), and to raise the \xintError: FactorialOfTooBigNumber for argument larger than 1000000 (rather than 1000000000). With 1.09a, \xintFac uses \xintnum.

### 35.55 \xintPow

1.02 modified the `\XINT_posprod` routine, and this meant that the original version was moved here and renamed to `\XINT_pow_posprod`, as it was well adapted for computing powers. Then I moved in 1.03 the special variants of multiplication (hence of addition) which were needed to earlier in this file. Modified in 1.06, the exponent is given to a `\numexpr` rather than twice expanded. `\xintnum` added in 1.09a. However this added some overhead to some inner macros of the `\xintPow` routine of `xintfrac.sty`... we did the similar things correctly for `\xintiadd` etc, but not here, so 1.09f has now the necessary `\xintiipow`.

Routine de produit servant pour le calcul des puissances. Chaque nouveau terme est plus grand que ce qui a déjà été calculé. Par conséquent on a intérêt à le conserver en second dans la routine de multiplication, donc le précédent calcul a intérêt à avoir été donné sur  $4n$ , à l'envers. Il faut donc modifier la multiplication pour qu'elle fasse cela. Ce qui oblige à utiliser une version spéciale de l'addition également.

jusqu'à présent c'est facile.
minusplus signifie B < 0, A > 0
plusminus signifie B > 0, A < 0
Ici #3#1 correspond au diviseur B et #4#2 au divisé A.

Cases with B<0 or especially A<0 are treated sub-optimally in terms of post-
processing, things get reversed which could have been produced directly in the
wanted order, but A,B>0 is given priority for optimization.

La soustraction spéciale.

Elle fait l'expansion (une fois pour le premier, deux fois pour le second) de ses arguments. Ceux-ci doivent être à l'envers sur 4n. De plus on sait a priori que le second est > le premier. Et le résultat de la différence est renvoyé **avec la même longueur que le second** (donc avec des leading zéros éventuels), et *à l'endroit*.

### 35.63 $\text{\xintDSH}$ , $\text{\xintDSHr}$

DECIMAL SHIFTS  $\text{\xintDSH}$  {x}{A}  
si  $x \leq 0$ , fait  $A \rightarrow A \cdot 10^{|x|}$ . v1.03 corrige l'oversight pour  $A=0.n$  si  $x > 0$ , et  
 $A \geq 0$ , fait  $A \rightarrow \text{quo}(A, 10^{|x|})$   
si  $x > 0$ , et  $A < 0$ , fait  $A \rightarrow -\text{quo}(-A, 10^{|x|})$   
(donc pour  $x > 0$  c'est comme DSR itéré  $x$  fois)  
 $\text{\xintDSHr}$  donne le 'reste' (si  $x \leq 0$  donne zéro).

Release 1.06 now feeds  $x$  to a  $\text{\numexpr}$  first. I will revise the legacy code on another occasion.

### 35.64 \xintDSx

Je fais cette routine pour la version 1.01, après modification de \xintDecSplit. Dorénavant \xintDSx fera appel à \xintDecSplit et de même \xintDSH fera appel à \xintDSx. J'ai donc supprimé entièrement l'ancien code de \xintDSH et re-écrit entièrement celui de \xintDecSplit pour x positif.

```

--> Attention le cas x=0 est traité dans la même catégorie que x > 0 <--
si x < 0, fait A -> A.10^(|x|)
si x >= 0, et A >=0, fait A -> {quo(A,10^(x))}{rem(A,10^(x))}
si x >= 0, et A < 0, d'abord on calcule {quo(-A,10^(x))}{rem(-A,10^(x))} puis, si le premier n'est pas nul on lui donne le signe -
si le premier est nul on donne le signe - au second.

```

On peut donc toujours reconstituer l'original A par  $10^x Q \pm R$  où il faut prendre le signe plus si Q est positif ou nul et le signe moins si Q est strictement négatif.

Release 1.06 has a faster and more compactly coded \XINT\_dsx\_zeroloop. Also, x is now given to a \numexpr. The earlier code should be then simplified, but I leave as is for the time being.

In 1.07, I decide to modify the coding of \XINT\_dsx\_zeroloop, to avoid impacting the input stack (which prevented doing truncation or rounding or float with more than eight times the size of input stack;  $40000 = 8 \times 5000$  digits on my installation.) I think this was the only place in the code with such non tail recursion, as I recall being careful to avoid problems within the Factorial and Power routines, but I would need to check. Too tired now after having finished \xintexpr, \xintNewExpr, and \xintfloatexpr!

### 35.65 **\xintDecSplit, \xintDecSplitL, \xintDecSplitR**

#### DECIMAL SPLIT

The macro `\xintDecSplit {x}{A}` first replaces A with  $|A|$  (\*) This macro cuts the number into two pieces L and R. The concatenation LR always reproduces  $|A|$ , and R may be empty or have leading zeros. The position of the cut is specified by the first argument x. If x is zero or positive the cut location is x slots to the left of the right end of the number. If x becomes equal to or larger than the length of the number then L becomes empty. If x is negative the location of the cut is  $|x|$  slots to the right of the left end of the number.

(\*) warning: this may change in a future version. Only the behavior for A non-negative is guaranteed to remain the same.

v1.05a: `\XINT_split_checksizex` does not compute the length anymore, rather the error will be from a `\numexpr`; but the limit of 999999999 does not make much sense.

v1.06: Improvements in `\XINT_split_fromleft_loop`, `\XINT_split_fromright_loop` and related macros. More readable coding, speed gains. Also, I now feed immediately a `\numexpr` with x. Some simplifications should probably be made to the code, which is kept as is for the time being.

1.09e pays attention to the use of `xintiabs` which acquired in 1.09a the `xintnum` overhead. So `xintiabs` rather without that overhead.

### 35.70 *\xintiSqrt*, *\xintiSquareRoot*

v1.08. 1.09a uses *\xintnum*. Very embarrassing to discover at the time of 1.09e that *\xintiSqrt {0}* was buggy!

Some overhead was added inadvertently in 1.09a to inner routines when *\xintquo* and *\xintidivision* were promoted to use *\xintnum*. Reverted in 1.09f.

### 36.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection is copied from HEIKO OBERDIEK's packages, and adapted here to check for previous loading of the master **xint** package.

The method for catcodes is slightly different, but still directly inspired by these packages.

## 37 Package *xintgcd* implementation

The commenting is currently (2013/12/18) very sparse. Release 1.09h has modified a bit the `\xintTypesetEuclideAlgorithm` and `\xintTypesetBezoutAlgorithm` layout with respect to line indentation in particular. And they use the `xinttools` `\xintloop` rather than the Plain  $\text{\TeX}$  or  $\text{\LaTeX}$ 's `\loop`.

### 37.1 Catcodes, $\varepsilon$ - $\text{\TeX}$ and reload detection

The code for reload detection is copied from HEIKO OBERDIEK's packages, and adapted here to check for previous loading of the master `xint` package.

The method for catcodes is slightly different, but still directly inspired by these packages.

78 \ProvidesPackage{xintgcd}%
79  [2013/12/18 v1.09i Euclide algorithm with xint package (jfB)]%

```

### 37.5 \xintGCD

The macros of 1.09a benefits from the `\xintnum` which has been inserted inside `\xintiabs` in **xint**; this is a little overhead but is more convenient for the user and also makes it easier to use into `\xint-`expressions.

```

80 \def\xintGCD {\romannumeral0\xintgcd }%

### 38.1 Catcodes, $\varepsilon$ -**T<sub>E</sub>X** and reload detection

The code for reload detection is copied from HEIKO OBERDIEK's packages, and adapted here to check for previous loading of the master **xint** package.

The method for catcodes is slightly different, but still directly inspired by these packages.

```

1 \begingroup\catcode61\catcode48\catcode32=10\relax%

### 38.7 *\XINT\_outfrac*

1.06a version now outputs  $0/1[0]$  and not  $0[0]$  in case of zero. More generally all macros have been checked in *xintfrac*, *xintseries*, *xintcfrac*, to make sure the output format for fractions was always  $A/B[n]$ . (except *\xintIrr*, *\xintJrr*, *\xintRawWithZeros*)

The problem with statements like those in the previous paragraph is that it is hard to maintain consistencies across releases.

```

### 38.23 \xintE

added with 1.07, together with support for ‘floats’. The fraction comes first here, contrarily to `\xintTrunc` and `\xintRound`.

`\xintfE` (1.07) and `\xintiE` (1.09i) for `\xintexpr` and cousins. It is quite annoying that `\numexpr` does not know how to deal correctly with `- : \numexpr -(1)\relax` is illegal!

the 1.07 `\xintE` put directly its second argument in a `\numexpr`. The `\xintfE` first uses `\xintNum` on it, this necessary for use in `\xintexpr`. (but then one cannot use directly infix notation in the second argument of `\xintfE`)

1.09i also adds `\xintFloatE` and modifies `\XINTinFloatfE`, although currently the latter is only used from `\xintfloatexpr` hence always with `\XINTdigits`, it comes equipped with its first argument withing brackets as the other `\XINTinFloat...` macros.

### 38.24 \xintIrr

1.04 fixes a buggy `\xintIrr {0}`. 1.05 modifies the initial parsing and post-processing to use `\xintrawithzeros` and to more quickly deal with an input denominator equal to 1. 1.08 version does not remove a /1 denominator.

### 38.25 \xintNum

This extension of the xint original `xintNum` is added in 1.05, as a synonym to `\xintIrr`, but raising an error when the input does not evaluate to an integer. Usable with not too much overhead on integer input as `\xintIrr` checks quickly for a denominator equal to 1 (which will be put there by the `\XINT_infrac` called by `\xintrawwithzeros`). This way, macros such as `\xintQuo` can be modified with minimal overhead to accept fractional input as long as it evaluates to an integer.

```
710 \def\xintNum {\romannumeral0\xintnum }%
711 \def\xintnum #1{\expandafter\XINT_intcheck\romannumeral0\xintirr {#1}\Z }%

### 38.28 \xintTfrac

1.09i, for `frac` in `\xintexpr`. And `\xintFrac` is already assigned. T for truncation. However, potentially not very efficient with numbers in scientific notations, with big exponents. Will have to think it again some day. I hesitated how to call the macro. Same convention as in maple, but some people reserve fractional part to  $x - \text{floor}(x)$ . Also, not clear if I had to make it negative (or zero) if  $x < 0$ , or rather always positive. There should be in fact such a thing for each rounding function, `trunc`, `round`, `floor`, `ceil`.

```

788 \def\xintTfrac {\romannumeral0\xinttfrac }%
789 \def\xinttfrac #1%

### 38.33 \xintDigits

The `mathchardef` used to be called `\XINT_digits`, but for reasons originating in `\xintNewExpr`, release 1.09a uses `\XINTdigits` without underscore.

```

985 \mathchardef\XINTdigits 16
986 \def\xintDigits #1#2%
987     {\afterassignment \xint_gobble_i \mathchardef\XINTdigits=%
988 \def\xinttheDigits {\number\XINTdigits }%

```

### 38.34 \xintFloat

1.07. Completely re-written in 1.08a, with spectacular speed gains. The earlier version was seriously silly when dealing with inputs having a big power of ten. Again some modifications in 1.08b for a better treatment of cases with long explicit numerators or denominators. Macro `\xintFloat:csv` added in 1.09 for use by `xintexpr`. Here again some inner macros used the `\xintquo` with extra `\xintnum` overhead in 1.09a, reverted in 1.09f.

### 38.36 \XINT\_inFloat

1.07. Completely rewritten in 1.08a for immensely greater efficiency when the power of ten is big: previous version had some very serious bottlenecks arising from the creation of long strings of zeros, which made things such as  $2^{999999}$  completely impossible, but now even  $2^{99999999}$  with 24 significant digits is no problem! Again (slightly) improved in 1.08b.

For convenience in *xintexpr.sty* (special rôle of the underscore in *\xintNewExpr*) 1.09a adds *\XINTinFloat*. I also decide in 1.09a not to use anymore *\romannumerals-0* mais *\romannumeral0* in the float routines, for consistency of style.

Here again some inner macros used the *\xintquo* with extra *\xintnum* overhead in 1.09a, reverted in 1.09f.

### 38.43 \xintPow

Modified in 1.06 to give the exponent to a \numexpr.

With 1.07 and for use within the \xintexpr parser, we must allow fractions (which are integers in disguise) as input to the exponent, so we must have a variant which uses \xintNum and not only \numexpr for normalizing the input. Hence the \xintfPow here. 1.08b: well actually I think that with xintfrac.sty loaded the exponent should always be allowed to be a fraction giving an integer. So I do as for \xintFac, and remove here the duplicated. The \xintexpr can thus use directly \xintPow.

```

### 38.44 \xintFac

1.07: to be used by the `\xintexpr` scanner which needs to be able to apply `\xintFac` to a fraction which is an integer in disguise; so we use `\xintNum` and not only `\numexpr`. Je modifie cela dans 1.08b, au lieu d'avoir un `\xintfFac` spécialement pour `\xintexpr`, tout simplement j'étends `\xintFac` comme les autres macros, pour qu'elle utilise `\xintNum`.

```

### 38.60 \xintCmp

Rewritten completely in 1.08a to be less dumb when comparing fractions having big powers of tens. Incredibly, it seems that 1.08b introduced a bug in delimited arguments making the macro just non-functional when one of the input was zero! I did not detect this until working on release 1.09a, somehow I had not tested that \xintCmp just did NOT work! I must have done some last minute change...

```

### 39.1 Catcodes, $\varepsilon$ -TeX and reload detection

The code for reload detection is copied from HEIKO OBERDIEK's packages, and adapted here to check for previous loading of the **xintfrac** package.

The method for catcodes is slightly different, but still directly inspired by these packages.

```

## 39.5 \xintSeries

Modified in 1.06 to give the indices first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

### 39.7 \xintPowerSeries

The 1.03 version was very lame and created a build-up of denominators. The Horner scheme for polynomial evaluation is used in 1.04, this cures the denominator problem and drastically improves the efficiency of the macro. Modified in 1.06 to give the indices first to a `\numexpr` rather than expanding twice. I just use `\the\numexpr` and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

```

185 {%
186   \xint_powseries_loop_i {#4{#3}}{#2}{#3}{#4}{#1}%
187 }%

```

### 39.9 \xintRationalSeries

This computes  $F(a) + \dots + F(b)$  on the basis of the value of  $F(a)$  and the ratios  $F(n)/F(n-1)$ . As in *\xintPowerSeries* we use an iterative scheme which has the great advantage to avoid denominator build-up. This makes exact computations possible with exponential type series, which would be completely inaccessible to *\xintSeries*. #1=a, #2=b, #3=F(a), #4=ratio function Modified in 1.06 to give the indices first to a *\numexpr* rather than expanding twice. I just use *\the\numexpr* and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

```

```

### 39.10 \xintRationalSeriesX

```
a,b,initial,ratiofunction,x
```

This computes  $F(a,x) + \dots + F(b,x)$  on the basis of the value of  $F(a,x)$  and the ratios  $F(n,x)/F(n-1,x)$ . The argument  $x$  is first expanded and it is the value resulting from this which is used then throughout. The initial term  $F(a,x)$  must be defined as one-parameter macro which will be given  $x$ . Modified in 1.06 to give the indices first to a  $\text{\numexpr}$  rather than expanding twice. I just use  $\text{\the}\text{\numexpr}$  and maintain the previous code after that. 1.08a adds the forgotten optimization following that previous change.

## 40.1 Catcodes, ε-T<sub>E</sub>X and reload detection

The code for reload detection is copied from HEIKO OBERDIEK's packages, and adapted here to check for previous loading of the **xintfrac** package.

The method for catcodes is slightly different, but still directly inspired by these packages.

```

## 41 Package `xintexpr` implementation

The first version was released in June 2013. I was greatly helped in this task of writing an expandable parser of infix operations by the comments provided in `13fp-parse.dtx`. One will recognize in particular the idea of the ‘until’ macros; I have not looked into the actual `13fp` code beyond the very useful comments provided in its documentation.

A main worry was that my data has no a priori bound on its size; to keep the code reasonably efficient, I experimented with a technique of storing and retrieving data expandably as *names* of control sequences. Intermediate computation results are stored as control sequences `\.=a/b[n]`.

Another peculiarity is that the input is allowed to contain (but only where the scanner looks for a number or fraction) material within braces `{...}`. This will be expanded completely and must give an integer, decimal number or fraction (not in scientific notation). Conversely any fraction (or macro giving on expansion one such; this does not apply to intermediate computation results, only to user input) in the `A/B[n]` format with the brackets **must** be enclosed in such braces, square brackets are not acceptable by the expression parser.

These two things are a bit *experimental* and perhaps I will opt for another approach at a later stage. To circumvent the potential hash-table impact of the `\.=a/b[n]` I have provided the macro creators `\xintNewExpr` and `\xintNewFloatExpr`.

Roughly speaking, the parser mechanism is as follows: at any given time the last found “operator” has its associated `until` macro awaiting some news from the token flow; first `getnext` expands forward in the hope to construct some number, which may come from a parenthesized sub-expression, from some braced material, or from a digit by digit scan. After this number has been formed the next operator is looked for by the `getop` macro. Once `getop` has finished its job, `until` is presented with three tokens: the first one is the precedence level of the new found operator (which may be an end of expression marker), the second is the operator character token (earlier versions had here already some macro name,

but in order to keep as much common code to `expr` and `floatexpr` common as possible, this was modified) of the new found operator, and the third one is the newly found number (which was encountered just before the new operator).

The `until` macro of the earlier operator examines the precedence level of the new found one, and either executes the earlier operator (in the case of a binary operation, with the found number and a previously stored one) or it delays execution, giving the hand to the `until` macro of the operator having been found of higher precedence.

A minus sign acting as prefix gets converted into a (unary) operator inheriting the precedence level of the previous operator.

Once the end of the expression is found (it has to be marked by a `\relax`) the final result is output as four tokens: the first one a catcode 11 exclamation mark, the second one an error generating macro, the third one a printing macro and the fourth is `\.=a/b[n]`. The prefix `\xintthe` makes the output printable by killing the first two tokens.

Version 1.08b [2013/06/14] corrected a problem originating in the attempt to attribute a special rôle to braces: expansion could be stopped by space tokens, as various macros tried to expand without grabbing what came next. They now have a doubled `\romannumeral-`0`.

Version 1.09a [2013/09/24] has a better mechanism regarding `\xintthe`, more commenting and better organization of the code, and most importantly it implements functions, comparison operators, logic operators, conditionals. The code was reorganized and expansion proceeds a bit differently in order to have the `_getnext` and `_getop` codes entirely shared by `\xintexpr` and `\xintfloatexpr`. `\xintNewExpr` was rewritten in order to work with the standard macro parameter character `#`, to be catcode protected and to also allow comma separated expressions.

Version 1.09c [2013/10/09] added the `bool` and `togl` operators, `\xintboolexpr`, and `\xintNewNumExpr`, `\xintNewBoolExpr`. The code for `\xintNewExpr` is shared with `float`, `num`, and `bool`-expressions. Also the precedence level of the postfix operators `!`, `?` and `:` has been made lower than the one of functions.

Version 1.09i [2013/12/18] unpacks count and dimen registers and control sequences, with tacit multiplication. It has also made small improvements (speed gains in macro expansions in quite a few places).

Also, 1.09i implements `\xintiiexpr`, `\xinttheiiexpr`. New function `frac`. And encapsulation in `\csname..\endcsname` is done with `.=` as first tokens, so unpacking with `\string` can be done in a completely escape char agnostic way.

### 41.1 Catcodes, ε-T<sub>E</sub>X and reload detection

The code for reload detection is copied from HEIKO OBERDIEK's packages, and adapted here to check for previous loading of the **xintfrac** package.

The method for catcodes is slightly different, but still directly inspired by these packages.

```

## 41.5 Encapsulation in pseudo cs names, helper macros

1.09i uses `.` for encapsulation, thus allowing `\escapechar` to be anything (all previous releases were with `,`, so `\escapechar 46` was forbidden). Besides, the `\edef` definition has `\space` already expanded, perhaps this will compensate a tiny bit the time penalty of `'.'` viz `'.'` in unlocking... well not really, I guess.

```

80 \def\xint_gob_til_! #1!{}% nota bene: ! is of catcode 11

87 \def\xint_UDxintrelaxfork #1\xint_relax #2#3\krof {#2}%
```

## 41.6 `\xintexpr`, `\xinttheexpr`, `\xintthe`, ...

`\xintthe` is defined with a parameter, I guess I wanted to make sure no stray space tokens could cause a problem.

With 1.09i, `\xintiexpr` replaces `\xintnumexpr` which is kept for compatibility but will be removed at some point. Should perhaps issue a warning, but well, people can also read the documentation. Also 1.09i removes `\xinttheeval`.

1.09i has re-organized the material here.

## 41.8 `\XINT_get_next: looking for a number`

June 14: 1.08b adds a second `\romannumeral-'0` to `\XINT_expr_getnext` in an attempt to solve a problem with space tokens stopping the `\romannumeral` and thus preventing expansion of the following token. For example: `1+ \the\cnta` caused a problem, as '`\the`' was not expanded. I did not define `\XINT_expr_getnext` as a macro with parameter (which would have cured preventively this), precisely to try to recognize brace pairs. The second `\romannumeral-'0` is added for the same reason in other places.

The get-next scans forward to find a number: after expansion of what comes next, an opening parenthesis signals a parenthesized sub-expression, a ! with catcode 11 signals there was there an `\xintexpr.. \relax` sub-expression (now evaluated), a minus is a prefix operator, a plus is silently ignored, a digit or decimal point signals to start gathering a number, braced material `{...}` is allowed and will be directly fed into a `\csname..\endcsname` for complete expansion which must delivers a (fractional) number, possibly ending in [n]; explicit square brackets must be enclosed into such braces. Once a number issues from the previous procedures, it is locked into a `\csname..\endcsname`, and the flow then proceeds

## 41 Package *xintexpr* implementation

with `\XINT_expr_getop` which will scan for an infix or postfix operator following the number.

A special `r^\ole` is played by underscores `_` for use with `\xintNewExpr` to input macro parameters.

Release 1.09a implements functions; the idea is that a letter (actually, anything not otherwise recognized!) triggers the function name gatherer, the comma is promoted to a binary operator of priority intermediate between parentheses and infix operators. The code had some other revisions in order for all the `_getnext` and `_getop` macros to now be shared by `\xintexpr` and `\xintflexexpr`.

1.09i now allows direct insertion of `\count`'s, `\dimen`'s and `\skip`'s which will be unpacked using `\number`.

1.09i speeds up a bit the recognition of a braced thing: the case of a single braced control sequence makes a third expansion mandatory, let's do it immediately and not wait. So macros got shuffled and modified a bit.

`\XINT_expr_unpackvariable` does not insert a `[0]` for compatibility with `\xintiiexpr`. A `[0]` would have made a bit faster `\xintexpr` macros when dealing with an unpacked count control sequence, as without it the `\xintnum` will be used in the parsing by `\xintfrac` macros when the number is used. But `[0]` is not accepted by most macros ultimately called by `\xintiiexpr`.

```

1.09a: In order to have this code shared by `\xintexpr` and `\xintfloatexpr`, I have moved to the until macros the responsibility to choose `expr` or `floatexpr`, hence here, the opening parenthesis for example can not be triggered directly as it would not know in which context it works. Hence the `\xint_c_xviii` `({})`. And also the mechanism of `\xintNewExpr` has been modified to allow use of `#`.

1.09i also has `\xintiiexpr`.

## 41.10 \XINT\_expr\_getop: looking for an operator

June 14 (1.08b): I add here a second \romannumeral-'0, because \XINT\_expr\_getnext and others try to expand the next token but without grabbing it.

This finds the next infix operator or closing parenthesis or postfix exclamation mark ! or expression end. It then leaves in the token flow <precedence> <operator> <locked number>. The <precedence> is generally a character command which thus stops expansion and gives back control to an \XINT\_expr\_until\_<op> command; or it is the minus sign which will be converted by a suitable \XINT\_expr\_checkifprefix\_<p> into an operator with a given inherited precedence. Earlier releases than 1.09c used tricks for the postfix !, ?, :, with <precedence> being in fact a macro to act immediately, and then re-activate \XINT\_expr\_getop.

In versions earlier than 1.09a the <operator> was already made in to a control sequence; but now it is a left as a token and will be (generally) converted by the until macro which knows if it is in a \xintexpr or an \xintfloatexpr. (or an \xintiexpr, since 1.09i)

1.09i allows \count's, \dimen's, \skip's with tacit multiplication.

```

298 \def\XINT_expr_getop #1% this #1 is the current locked computed value

### 41.15 ? as two-way conditional

New with 1.09a. Modified in 1.09c to have less precedence than functions. Code is cleaner as it does not play tricks with \_precedence. There is no associated until macro, because action is immediate once activated (only a previously scanned function can delay activation).

```
537 \let\XINT_expr_precedence_? \xint_c_x
538 \def \XINT_expr_op_? #1#2#3%
539 {%
540     \xintifZero{\XINT_expr_unlock #1}%

551         {\XINT_expr_getnext #3}%
552         {\XINT_expr_getnext #4}%
553 }%
554 \let\XINT_fexpr_op_:\XINT_expr_op_:
555 \let\XINT_iexpr_op_:\XINT_expr_op_:
```

### 41.17 ! as postfix factorial operator

The factorial is currently the exact one, there is no float version. Starting with 1.09c, it has lower priority than functions, it is not executed immediately anymore. The code is cleaner and does not abuse \_precedence, but does assign it a true level. There is no until macro, because the factorial acts on what precedes it.

```
556 \let\XINT_expr_precedence_! \xint_c_x
557 \def\XINT_expr_op_! #1{\expandafter\XINT_expr_getop
558     \csname .=\xintFac{\XINT_expr_unlock #1}\endcsname }%

### 41.19 *\xintNewExpr*, *\xintNewFloatExpr*...

Rewritten in 1.09a. Now, the parameters of the formula are entered in the usual way by the user, with # not \_. And \_ is assigned to make macros not expand. This way, : is freed, as we now need it for the ternary operator. (on numeric data; if use with macro parameters, should be coded with the functionn ifsgn , rather)

Code unified in 1.09c, and *\xintNewNumExpr*, *\xintNewBoolExpr* added. 1.09i renames *\xintNewNumExpr* to *\xintNewIExpr*, and defines *\xintNewIIExpr*.

```

1.09i has added `\escapechar 92`, as `\meaning` is used in `\XINT_NewExpr`, and a non-existent escape-char would be a problem with `\scantokens`. Also `\catcode32` is set to 10 in `\xintexprSafeCatcodes` for being extra-safe.

```
